This programming manual provides information for application and system-level software developers. It gives a full description of the STM32F10xxx Cortex™-M3 processor programming model, instruction set and core peripherals.

The STM32F10xxx Cortex™-M3 processor is a high performance 32-bit processor designed for the microcontroller market. It offers significant benefits to developers, including:

- Outstanding processing performance combined with fast interrupt handling
- Enhanced system debug with extensive breakpoint and trace capabilities
- Efficient processor core, system and memories
- Ultra-low power consumption with integrated sleep modes
- Platform security

1 About this document

This document provides the information required for application and system-level software development. It does not provide information on debug components, features, or operation. This material is for microcontroller software and hardware engineers, including those who have no experience of ARM products.

1.1 Typographical conventions

The typographical conventions used in this document are:

italic Highlights important notes, introduces special terminology, denotes internal cross-references, and citations.

< and > Enclose replaceable terms for assembler syntax where they appear in code or code fragments. For example:

LDRSB<cond> <Rt>, [<Rn>, #<offset>]

1.2 List of abbreviations for registers

The following abbreviations are used in register descriptions:

read/write (rw) Software can read and write to these bits.
read-only (r) Software can only read these bits.
write-only (w) Software can only write to this bit. Reading the bit returns the reset value.
read/clear (rc_w1) Software can read as well as clear this bit by writing 1. Writing ‘0’ has no effect on the bit value.
read/clear (rc_w0) Software can read as well as clear this bit by writing 0. Writing ‘1’ has no effect on the bit value.
toggle (t) Software can only toggle this bit by writing ‘1’. Writing ‘0’ has no effect.
Reserved (Res.) Reserved bit, must be kept at reset value.

1.3 About the STM32 Cortex-M3 processor and core peripherals

The Cortex-M3 processor is built on a high-performance processor core, with a 3-stage pipeline Harvard architecture, making it ideal for demanding embedded applications. The processor delivers exceptional power efficiency through an efficient instruction set and extensively optimized design, providing high-end processing hardware including single-cycle 32x32 multiplication and dedicated hardware division.
To facilitate the design of cost-sensitive devices, the Cortex-M3 processor implements tightly-coupled system components that reduce processor area while significantly improving interrupt handling and system debug capabilities. The Cortex-M3 processor implements a version of the Thumb\textsuperscript{®} instruction set, ensuring high code density and reduced program memory requirements. The Cortex-M3 instruction set provides the exceptional performance expected of a modern 32-bit architecture, with the high code density of 8-bit and 16-bit microcontrollers.

The Cortex-M3 processor closely integrates a configurable nested interrupt controller (NVIC), to deliver industry-leading interrupt performance. The NVIC includes a non-maskable interrupt (NMI), and provides up to 256 interrupt priority levels. The tight integration of the processor core and NVIC provides fast execution of interrupt service routines (ISRs), dramatically reducing the interrupt latency. This is achieved through the hardware stacking of registers, and the ability to suspend load-multiple and store-multiple operations. Interrupt handlers do not require any assembler stubs, removing any code overhead from the ISRs. Tail-chaining optimization also significantly reduces the overhead when switching from one ISR to another.

To optimize low-power designs, the NVIC integrates with the sleep modes, that include a deep sleep function that enables the STM32 to enter STOP or STDBY mode.

1.3.1 System level interface

The Cortex-M3 processor provides multiple interfaces using AMBA\textsuperscript{®} technology to provide high speed, low latency memory accesses. It supports unaligned data accesses and implements atomic bit manipulation that enables faster peripheral controls, system spinlocks and thread-safe Boolean data handling.

1.3.2 Integrated configurable debug

The Cortex-M3 processor implements a complete hardware debug solution. This provides high system visibility of the processor and memory through either a traditional JTAG port or a 2-pin *Serial Wire Debug* (SWD) port that is ideal for small package devices.
For system trace the processor integrates an **Instrumentation Trace Macrocell** (ITM) alongside data watchpoints and a profiling unit. To enable simple and cost-effective profiling of the system events these generate, a **Serial Wire Viewer** (SWV) can export a stream of software-generated messages, data trace, and profiling information through a single pin.

The optional **Embedded Trace Macrocell™** (ETM) delivers unrivalled instruction trace capture in an area far smaller than traditional trace units, enabling many low cost MCUs to implement full instruction trace for the first time.

### 1.3.3 Cortex-M3 processor features and benefits summary

- Tight integration of system peripherals reduces area and development costs
- Thumb instruction set combines high code density with 32-bit performance
- Code-patch ability for ROM system updates
- Power control optimization of system components
- Integrated sleep modes for low power consumption
- Fast code execution permits slower processor clock or increases sleep mode time
- Hardware division and fast multiplier
- Deterministic, high-performance interrupt handling for time-critical applications
- Extensive debug and trace capabilities:
  - Serial Wire Debug and Serial Wire Trace reduce the number of pins required for debugging and tracing.
1.3.4 Cortex-M3 core peripherals

These are:

**Nested vectored interrupt controller**

The *nested vectored interrupt controller* (NVIC) is an embedded interrupt controller that supports low latency interrupt processing.

**System control block**

The *system control block* (SCB) is the programmers model interface to the processor. It provides system implementation information and system control, including configuration, control, and reporting of system exceptions.

**System timer**

The system timer, SysTick, is a 24-bit count-down timer. Use this as a Real Time Operating System (RTOS) tick timer or as a simple counter.
2 The Cortex-M3 processor

2.1 Programmers model

This section describes the Cortex-M3 programmers model. In addition to the individual core register descriptions, it contains information about the processor modes and privilege levels for software execution and stacks.

2.1.1 Processor mode and privilege levels for software execution

The processor modes are:

- **Thread mode**: Used to execute application software. The processor enters Thread mode when it comes out of reset.
- **Handler mode**: Used to handle exceptions. The processor returns to Thread mode when it has finished exception processing.

The privilege levels for software execution are:

- **Unprivileged**: The software:
  - Has limited access to the MSR and MRS instructions, and cannot use the CPS instruction
  - Cannot access the system timer, NVIC, or system control block
  - Might have restricted access to memory or peripherals.
  
  *Unprivileged software executes at the unprivileged level.*

- **Privileged**: The software can use all the instructions and has access to all resources.
  
  *Privileged software executes at the privileged level.*

In Thread mode, the CONTROL register controls whether software execution is privileged or unprivileged, see **CONTROL register on page 22**. In Handler mode, software execution is always privileged.

Only privileged software can write to the CONTROL register to change the privilege level for software execution in Thread mode. Unprivileged software can use the SVC instruction to make a *supervisor call* to transfer control to privileged software.

2.1.2 Stacks

The processor uses a full descending stack. This means the stack pointer indicates the last stacked item on the stack memory. When the processor pushes a new item onto the stack, it decrements the stack pointer and then writes the item to the new memory location. The processor implements two stacks, the *main stack* and the *process stack*, with independent copies of the stack pointer, see **Stack pointer on page 16**.
In Thread mode, the CONTROL register controls whether the processor uses the main stack or the process stack, see CONTROL register on page 22. In Handler mode, the processor always uses the main stack. The options for processor operations are:

Table 1. Summary of processor mode, execution privilege level, and stack use options

<td>See description</td>
<td>Stack pointer on page 16</td>
</tr>
<tr>
<td>PSP</td>
<td>read-write</td>
<td>Either Unknown</td>
<td>Stack pointer on page 16</td>
<td></td>
</tr>
</tbody>
</table>
General-purpose registers

R0-R12 are 32-bit general-purpose registers for data operations.

Stack pointer

The Stack Pointer (SP) is register R13. In Thread mode, bit[1] of the CONTROL register indicates the stack pointer to use:

- 0 = Main Stack Pointer (MSP). This is the reset value.
- 1 = Process Stack Pointer (PSP).

On reset, the processor loads the MSP with the value from address 0x00000000.

Link register

The Link Register (LR) is register R14. It stores the return information for subroutines, function calls, and exceptions. On reset, the processor loads the LR value 0xFFFFFFFF.

Program counter

The Program Counter (PC) is register R15. It contains the current program address. Bit[0] is always 0 because instruction fetches must be halfword aligned. On reset, the processor loads the PC with the value of the reset vector, which is at address 0x00000004.
Program status register

The *Program Status Register* (PSR) combines:

- *Application Program Status Register* (APSR)
- *Interrupt Program Status Register* (IPSR)
- *Execution Program Status Register* (EPSR)

These registers are mutually exclusive bitfields in the 32-bit PSR. The bit assignments are as shown in *Figure 3* and *Figure 4*.

**Figure 3. APSR, IPSR and EPSR bit assignments**

Access these registers individually or as a combination of any two or all three registers, using the register name as an argument to the MSR or MRS instructions. For example:

- Read all of the registers using PSR with the MSR instruction
- Write to the APSR using APSR with the MSR instruction.

The PSR combinations and attributes are:

**Table 3. PSR register combinations**

<table>
<thead>
<tr>
<th>Register</th>
<th>Type</th>
<th>Combination</th>
</tr>
</thead>
<tbody>
<tr>
<td>PSR</td>
<td>read-write(1), (2)</td>
<td>APSR, EPSR, and IPSR</td>
</tr>
<tr>
<td>IEPSR</td>
<td>read-only</td>
<td>EPSR and IPSR</td>
</tr>
<tr>
<td>IAPSR</td>
<td>read-write(1)</td>
<td>APSR and IPSR</td>
</tr>
<tr>
<td>EAPSR</td>
<td>read-write(2)</td>
<td>APSR and EPSR</td>
</tr>
</tbody>
</table>

1. The processor ignores writes to the IPSR bits.
2. Reads of the EPSR bits return zero, and the processor ignores writes to these bits.

See the instruction descriptions *MRS on page 101* and *MSR on page 102* for more information about how to access the program status registers.
Application program status register

The APSR contains the current state of the condition flags from previous instruction executions. See the register summary in Table 2 on page 15 for its attributes. The bit assignments are:

Table 4. APSR bit definitions

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 31:9</td>
<td>Reserved</td>
</tr>
<tr>
<td>Bits 8:0</td>
<td><strong>ISR_NUMBER:</strong>&lt;br&gt;This is the number of the current exception:&lt;br&gt;0: Thread mode&lt;br&gt;1: Reserved&lt;br&gt;2: NMI&lt;br&gt;3: Hard fault&lt;br&gt;4: Memory management fault&lt;br&gt;5: Bus fault&lt;br&gt;6: Usage fault&lt;br&gt;7: Reserved&lt;br&gt;....&lt;br&gt;10: Reserved&lt;br&gt;11: SVCall&lt;br&gt;12: Reserved for Debug&lt;br&gt;13: Reserved&lt;br&gt;14: PendSV&lt;br&gt;15: SysTick&lt;br&gt;16: IRQ0&lt;sup&gt;(1)&lt;/sup&gt;&lt;br&gt;....&lt;br&gt;83: IRQ67&lt;sup&gt;(1)&lt;/sup&gt;&lt;br&gt;see <em>Exception types on page 34</em> for more information.</td>
</tr>
</tbody>
</table>

---

1. See STM32 product reference manual/datasheet for more information on interrupt mapping
Execution program status register

The EPSR contains the Thumb state bit, and the execution state bits for either the:

- **If-Then (IT) instruction**
- **Interruptible-Continuable Instruction (ICI) field** for an interrupted load multiple or store multiple instruction.

See the register summary in Table 2 on page 15 for the EPSR attributes. The bit assignments are:

Table 6. EPSR bit definitions

<table>
<thead>
<tr>
<th>Bits 31:27</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bits 26:25, 15:10</td>
<td>ICI: Interruptible-continuable instruction bits</td>
</tr>
<tr>
<td></td>
<td>See Interruptible-continuable instructions on page 20.</td>

<td>Always set to 1.</td>
</tr>
<tr>
<td>Bits 23:16</td>
<td>Reserved.</td>
</tr>
<tr>
<td>Bits 9:0</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

Attempts to read the EPSR directly through application software using the MSR instruction always return zero. Attempts to write the EPSR using the MSR instruction in application software are ignored. Fault handlers can examine EPSR value in the stacked PSR to indicate the operation that is at fault. See Section 2.3.7: Exception entry and return on page 38

Interruptible-continuable instructions

When an interrupt occurs during the execution of an LDM or STM instruction, the processor:

- Stops the load multiple or store multiple instruction operation temporarily
- Stores the next register operand in the multiple operation to EPSR bits[15:12].

After servicing the interrupt, the processor:

- Returns to the register pointed to by bits[15:12]
- Resumes execution of the multiple load or store instruction.

When the EPSR holds ICI execution state, bits[26:25,11:10] are zero.

If-Then block

The If-Then block contains up to four instructions following a 16-bit IT instruction. Each instruction in the block is conditional. The conditions for the instructions are either all the same, or some can be the inverse of others. See IT on page 95 for more information.

Exception mask registers

The exception mask registers disable the handling of exceptions by the processor. Disable exceptions where they might impact on timing critical tasks.

To access the exception mask registers use the MSR and MRS instructions, or the CPS instruction to change the value of PRIMASK or FAULTMASK. See MRS on page 101, MSR on page 102, and CPS on page 99 for more information.
Priority mask register

The PRIMASK register prevents activation of all exceptions with configurable priority. See the register summary in Table 2 on page 15 for its attributes. Figure 5 shows the bit assignments.

Figure 5. PRIMASK bit assignments

<td>1: Prevents the activation of all exceptions except for NMI.</td>
</tr>
</tbody>
</table>

The processor clears the FAULTMASK bit to 0 on exit from any exception handler except the NMI handler.
Base priority mask register

The BASEPRI register defines the minimum priority for exception processing. When BASEPRI is set to a nonzero value, it prevents the activation of all exceptions with same or lower priority level as the BASEPRI value. See the register summary in Table 2 on page 15 for its attributes. Figure 7 shows the bit assignments.

Figure 7. BASEPRI bit assignments

</tr>
<tr>
<td>1: PSP is the current stack pointer.</td>
<td></td>
</tr>
<tr>
<td>In Handler mode this bit reads as zero and ignores writes.</td>
<td></td>
</tr>
</tbody>
</table>
Handler mode always uses the MSP, so the processor ignores explicit writes to the active stack pointer bit of the CONTROL register when in Handler mode. The exception entry and return mechanisms update the CONTROL register.

In an OS environment, it is recommended that threads running in Thread mode use the process stack and the kernel and exception handlers use the main stack.

By default, Thread mode uses the MSP. To switch the stack pointer used in Thread mode to the PSP, use the MSR instruction to set the Active stack pointer bit to 1, see MSR on page 102.

When changing the stack pointer, software must use an ISB instruction immediately after the MSR instruction. This ensures that instructions after the ISB execute using the new stack pointer. See ISB on page 101.

### 2.1.4 Exceptions and interrupts

The Cortex-M3 processor supports interrupts and system exceptions. The processor and the Nested Vectored Interrupt Controller (NVIC) prioritize and handle all exceptions. An exception changes the normal flow of software control. The processor uses handler mode to handle all exceptions except for reset. See Exception entry on page 39 and Exception return on page 40 for more information.

The NVIC registers control interrupt handling. See Memory protection unit (MPU) on page 106 for more information.

### 2.1.5 Data types

The processor:
- Supports the following data types:
  - 32-bit words
  - 16-bit halfwords
  - 8-bit bytes
- supports 64-bit data transfer instructions.
- manages all memory accesses (data memory, instruction memory and Private Peripheral Bus (PPB)) as little-endian. See Memory regions, types and attributes on page 26 for more information.
2.1.6 The Cortex microcontroller software interface standard (CMSIS)

For a Cortex-M3 microcontroller system, the *Cortex Microcontroller Software Interface Standard* (CMSIS) defines:

- A common way to:
  - Access peripheral registers
  - Define exception vectors
- The names of:
  - The registers of the core peripherals
  - The core exception vectors
- A device-independent interface for RTOS kernels, including a debug channel

The CMSIS includes address definitions and data structures for the core peripherals in the Cortex-M3 processor. It also includes optional interfaces for middleware components comprising a TCP/IP stack and a Flash file system.

CMSIS simplifies software development by enabling the reuse of template code and the combination of CMSIS-compliant software components from various middleware vendors. Software vendors can expand the CMSIS to include their peripheral definitions and access functions for those peripherals.

This document includes the register names defined by the CMSIS, and gives short descriptions of the CMSIS functions that address the processor core and the core peripherals.

This document uses the register short names defined by the CMSIS. In a few cases these differ from the architectural short names that might be used in other documents.

The following sections give more information about the CMSIS:

- *Section 2.5.4: Power management programming hints on page 45*
- *Intrinsic functions on page 51*
- *The CMSIS mapping of the Cortex-M3 NVIC registers on page 120*
- *NVIC programming hints on page 128*
2.2 Memory model

This section describes the processor memory map, the behavior of memory accesses, and the bit-banding features. The processor has a fixed memory map that provides up to 4 GB of addressable memory.

The regions for SRAM and peripherals include bit-band regions. Bit-banding provides atomic operations to bit data, see Section 2.2.5: Bit-banding on page 29.

The processor reserves regions of the Private peripheral bus (PPB) address range for core peripheral registers, see Section 4.1: About the STM32 core peripherals on page 106.
2.2.1 Memory regions, types and attributes

The memory map splits the memory map into regions. Each region has a defined memory type, and some regions have additional memory attributes. The memory type and attributes determine the behavior of accesses to the region.

The memory types are:

- **Normal**: The processor can re-order transactions for efficiency, or perform speculative reads.

- **Device**: The processor preserves transaction order relative to other transactions to Device or Strongly-ordered memory.

- **Strongly-ordered**: The processor preserves transaction order relative to all other transactions.

The different ordering requirements for Device and Strongly-ordered memory mean that the memory system can buffer a write to Device memory, but must not buffer a write to Strongly-ordered memory.

The additional memory attributes include:

- **Execute Never (XN)**: Means the processor prevents instruction accesses. Any attempt to fetch an instruction from an XN region causes a memory management fault exception.
2.2.2 Memory system ordering of memory accesses

For most memory accesses caused by explicit memory access instructions, the memory system does not guarantee that the order in which the accesses complete matches the program order of the instructions, providing this does not affect the behavior of the instruction sequence. Normally, if correct program execution depends on two memory accesses completing in program order, software must insert a memory barrier instruction between the memory access instructions, see Section 2.2.4: Software ordering of memory accesses on page 28.

However, the memory system does guarantee some ordering of accesses to Device and Strongly-ordered memory. For two memory access instructions A1 and A2, if A1 occurs before A2 in program order, the ordering of the memory accesses caused by two instructions is:

Table 11. Ordering of memory accesses

<table>
<thead>
<tr>
<th>A1</th>
<th>A2</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal access</td>
<td></td>
</tr>
<tr>
<td>Device access</td>
<td></td>
</tr>
<tr>
<td>Normal access</td>
<td>-</td>
</tr>
<tr>
<td>Device access, non-shareable</td>
<td>-</td>
</tr>
<tr>
<td>Device access, shareable</td>
<td>-</td>
</tr>
<tr>
<td>Strongly ordered access</td>
<td>-</td>
</tr>
</tbody>
</table>

1. - means that the memory system does not guarantee the ordering of the accesses.
   < means that accesses are observed in program order, that is, A1 is always observed before A2.

2.2.3 Behavior of memory accesses

The behavior of accesses to each region in the memory map is:

Table 12. Memory access behavior

<table>
<thead>
<tr>
<th>Address range</th>
<th>Memory region</th>
<th>Memory type</th>
<th>XN</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x00000000- 0x1FFFFFFF</td>
<td>Code</td>
<td>Normal(^{(1)})</td>
<td>-</td>
<td>Executable region for program code. You can also put data here.</td>
</tr>
<tr>
<td>0x20000000- 0x3FFFFFFF</td>
<td>SRAM</td>
<td>Normal(^{(1)})</td>
<td>-</td>
<td>Executable region for data. You can also put code here. This region includes bit band and bit band alias areas, see Table 13 on page 29.</td>
</tr>
<tr>
<td>0x40000000- 0x5FFFFFFF</td>
<td>Peripheral</td>
<td>Device(^{(1)})</td>
<td>XN(^{(1)})</td>
<td>This region includes bit band and bit band alias areas, see Table 14 on page 29.</td>
</tr>
<tr>
<td>0x60000000- 0x9FFFFFFF</td>
<td>External RAM</td>
<td>Normal(^{(1)})</td>
<td>-</td>
<td>Executable region for data.</td>
</tr>
</tbody>
</table>
The Code, SRAM, and external RAM regions can hold programs. However, it is recommended that programs always use the Code region. This is because the processor has separate buses that enable instruction fetches and data accesses to occur simultaneously.

2.2.4 Software ordering of memory accesses

The order of instructions in the program flow does not always guarantee the order of the corresponding memory transactions. This is because:

- The processor can reorder some memory accesses to improve efficiency, providing this does not affect the behavior of the instruction sequence.
- The processor has multiple bus interfaces
- Memory or devices in the memory map have different wait states
- Some memory accesses are buffered or speculative.

Section 2.2.2: Memory system ordering of memory accesses on page 27 describes the cases where the memory system guarantees the order of memory accesses. Otherwise, if the order of memory accesses is critical, software must include memory barrier instructions to force that ordering. The processor provides the following memory barrier instructions:

<table>
<thead>
<tr>
<th>Address range</th>
<th>Memory region</th>
<th>Memory type</th>
<th>XN</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xA0000000-0xDFFFFFFF</td>
<td>External device</td>
<td>Device(^{(1)})</td>
<td>XN(^{(1)})</td>
<td>External Device memory</td>
</tr>
<tr>
<td>0xE0000000-0xE00FFFFF</td>
<td>Private Peripheral Bus</td>
<td>Strongly-ordered(^{(1)})</td>
<td>XN(^{(1)})</td>
<td>This region includes the NVIC, System timer, and system control block.</td>
</tr>
<tr>
<td>0xE0100000-0xFFFFFFFF</td>
<td>Memory mapped peripherals</td>
<td>Device(^{(1)})</td>
<td>XN(^{(1)})</td>
<td>This region includes all the STM32 standard peripherals.</td>
</tr>
</tbody>
</table>

1. See Memory regions, types and attributes on page 26 for more information.

Use memory barrier instructions in, for example:

- Vector table. If the program changes an entry in the vector table, and then enables the corresponding exception, use a DMB instruction between the operations. This ensures that if the exception is taken immediately after being enabled the processor uses the new exception vector.
● **Self-modifying code.** If a program contains self-modifying code, use an ISB instruction immediately after the code modification in the program. This ensures subsequent instruction execution uses the updated program.

● **Memory map switching.** If the system contains a memory map switching mechanism, use a DSB instruction after switching the memory map in the program. This ensures subsequent instruction execution uses the updated memory map.

● **Dynamic exception priority change.** When an exception priority has to change when the exception is pending or active, use DSB instructions after the change. This ensures the change takes effect on completion of the DSB instruction.

● **Using a semaphore in multi-master system.** If the system contains more than one bus master, for example, if another processor is present in the system, each processor must use a DMB instruction after any semaphore instructions, to ensure other bus masters see the memory transactions in the order in which they were executed.

Memory accesses to Strongly-ordered memory, such as the system control block, do not require the use of DMB instructions.

### 2.2.5 Bit-banding

A bit-band region maps each word in a bit-band alias region to a single bit in the bit-band region. The bit-band regions occupy the lowest 1 MB of the SRAM and peripheral memory regions.

The memory map has two 32 MB alias regions that map to two 1 MB bit-band regions:

- Accesses to the 32 MB SRAM alias region map to the 1 MB SRAM bit-band region, as shown in Table 13
- Accesses to the 32 MB peripheral alias region map to the 1 MB peripheral bit-band region, as shown in Table 14.

<table>
<thead>
<tr>
<th>Address range</th>
<th>Memory region</th>
<th>Instruction and data accesses</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x20000000-0x20FFFFFF</td>
<td>SRAM bit-band region</td>
<td>Direct accesses to this memory range behave as SRAM memory accesses, but this region is also bit addressable through bit-band alias.</td>
</tr>
<tr>
<td>0x22000000-0x23FFFFFF</td>
<td>SRAM bit-band alias</td>
<td>Data accesses to this region are remapped to bit band region. A write operation is performed as read-modify-write. Instruction accesses are not remapped.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Address range</th>
<th>Memory region</th>
<th>Instruction and data accesses</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x40000000-0x40FFFFFF</td>
<td>Peripheral bit-band region</td>
<td>Direct accesses to this memory range behave as peripheral memory accesses, but this region is also bit addressable through bit-band alias.</td>
</tr>
<tr>
<td>0x42000000-0x43FFFFFF</td>
<td>Peripheral bit-band alias</td>
<td>Data accesses to this region are remapped to bit-band region. A write operation is performed as read-modify-write. Instruction accesses are not permitted.</td>
</tr>
</tbody>
</table>

A word access to the SRAM or peripheral bit-band alias regions map to a single bit in the SRAM or peripheral bit-band region.
The following formula shows how the alias region maps onto the bit-band region:

\[
\text{bit\_word\_offset} = (\text{byte\_offset} \times 32) + (\text{bit\_number} \times 4)
\]

\[
\text{bit\_word\_addr} = \text{bit\_band\_base} + \text{bit\_word\_offset}
\]

Where:

- Bit\_word\_offset is the position of the target bit in the bit-band memory region.
- Bit\_word\_addr is the address of the word in the alias memory region that maps to the targeted bit.
- Bit\_band\_base is the starting address of the alias region.
- Byte\_offset is the number of the byte in the bit-band region that contains the targeted bit.
- Bit\_number is the bit position, 0-7, of the targeted bit.

*Figure 10 on page 30* shows examples of bit-band mapping between the SRAM bit-band alias region and the SRAM bit-band region:

- The alias word at 0x23FFFFE0 maps to bit[0] of the bit-band byte at 0x200FFFFFF: 0x23FFFFE0 = 0x22000000 + (0xFFFFF\*32) + (0\*4).
- The alias word at 0x23FFFFFC maps to bit[7] of the bit-band byte at 0x200FFFFFF: 0x23FFFFFC = 0x22000000 + (0xFFFFF\*32) + (7\*4).
- The alias word at 0x22000000 maps to bit[0] of the bit-band byte at 0x200000000: 0x220000000 = 0x220000000 + (0\*32) + (0 \*4).
- The alias word at 0x22000001C maps to bit[7] of the bit-band byte at 0x200000000: 0x22000001C = 0x220000000 + (0\*32) + (7\*4).

**Figure 10. Bit-band mapping**

Directly accessing an alias region

Writing to a word in the alias region updates a single bit in the bit-band region.
Bit[0] of the value written to a word in the alias region determines the value written to the targeted bit in the bit-band region. Writing a value with bit[0] set to 1 writes a 1 to the bit-band bit, and writing a value with bit[0] set to 0 writes a 0 to the bit-band bit.

Bits[31:1] of the alias word have no effect on the bit-band bit. Writing 0x01 has the same effect as writing 0xFF. Writing 0x00 has the same effect as writing 0x0E.

Reading a word in the alias region:
- 0x00000000 indicates that the targeted bit in the bit-band region is set to zero
- 0x00000001 indicates that the targeted bit in the bit-band region is set to 1

Directly accessing a bit-band region

Behavior of memory accesses on page 27 describes the behavior of direct byte, halfword, or word accesses to the bit-band regions.

2.2.6 Memory endianness

The processor views memory as a linear collection of bytes numbered in ascending order from zero. For example, bytes 0-3 hold the first stored word, and bytes 4-7 hold the second stored word.

Little-endian format

In little-endian format, the processor stores the least significant byte of a word at the lowest-numbered byte, and the most significant byte at the highest-numbered byte. See Figure 11 for an example.

Figure 11. Little-endian example
2.2.7 Synchronization primitives

The Cortex-M3 instruction set includes pairs of synchronization primitives. These provide a non-blocking mechanism that a thread or process can use to obtain exclusive access to a memory location. Software can use them to perform a guaranteed read-modify-write memory update sequence, or for a semaphore mechanism.

A pair of synchronization primitives comprises:

A Load-Exclusive instruction Used to read the value of a memory location, requesting exclusive access to that location.

A Store-Exclusive instruction Used to attempt to write to the same memory location, returning a status bit to a register. If this bit is:

0: it indicates that the thread or process gained exclusive access to the memory, and the write succeeds
1: it indicates that the thread or process did not gain exclusive access to the memory, and no write is performed

The pairs of Load-Exclusive and Store-Exclusive instructions are:

- The word instructions LDREX and STREX
- The halfword instructions LDREXH and STREXH
- The byte instructions LDREXB and STREXB.

Software must use a Load-Exclusive instruction with the corresponding Store-Exclusive instruction.

To perform a guaranteed read-modify-write of a memory location, software must:

1. Use a Load-Exclusive instruction to read the value of the location.
2. Update the value, as required.
3. Use a Store-Exclusive instruction to attempt to write the new value back to the memory location, and tests the returned status bit. If this bit is:

   0: The read-modify-write completed successfully,
   1: No write was performed. This indicates that the value returned at step 1 might be out of date. The software must retry the read-modify-write sequence,
Software can use the synchronization primitives to implement a semaphores as follows:

1. Use a Load-Exclusive instruction to read from the semaphore address to check whether the semaphore is free.

2. If the semaphore is free, use a Store-Exclusive to write the claim value to the semaphore address.

3. If the returned status bit from step 2 indicates that the Store-Exclusive succeeded then the software has claimed the semaphore. However, if the Store-Exclusive failed, another process might have claimed the semaphore after the software performed step 1.

The Cortex-M3 includes an exclusive access monitor, that tags the fact that the processor has executed a Load-Exclusive instruction.

The processor removes its exclusive access tag if:

- It executes a CLREX instruction
- It executes a Store-Exclusive instruction, regardless of whether the write succeeds.
- An exception occurs. This means the processor can resolve semaphore conflicts between different threads.

For more information about the synchronization primitive instructions, see LDREX and STREX on page 71 and CLREX on page 72.

### 2.2.8 Programming hints for the synchronization primitives

ANSI C cannot directly generate the exclusive access instructions. Some C compilers provide intrinsic functions for generation of these instructions:

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Intrinsic function</th>
</tr>
</thead>
<tbody>
<tr>
<td>LDREX, LDREXH, or LDREXB</td>
<td><code>unsigned int __ldrex(volatile void *ptr)</code></td>

</tr>
</tbody>
</table>

The actual exclusive access instruction generated depends on the data type of the pointer passed to the intrinsic function. For example, the following C code generates the require LDREXB operation:

```c
__ldrex((volatile char *) 0xFF);
```
2.3 Exception model

This section describes the exception model.

2.3.1 Exception states

Each exception is in one of the following states:

- **Inactive**: The exception is not active and not pending.
- **Pending**: The exception is waiting to be serviced by the processor. An interrupt request from a peripheral or from software can change the state of the corresponding interrupt to pending.
- **Active**: An exception that is being serviced by the processor but has not completed.
  
  *Note*: An exception handler can interrupt the execution of another exception handler. In this case both exceptions are in the active state.
- **Active and pending**: The exception is being serviced by the processor and there is a pending exception from the same source.

2.3.2 Exception types

The exception types are:

- **Reset**: Reset is invoked on power up or a warm reset. The exception model treats reset as a special form of exception. When reset is asserted, the operation of the processor stops, potentially at any point in an instruction. When reset is deasserted, execution restarts from the address provided by the reset entry in the vector table. Execution restarts as privileged execution in Thread mode.
- **NMI**: A NonMaskable Interrupt (NMI) can be signalled by a peripheral or triggered by software. This is the highest priority exception other than reset. It is permanently enabled and has a fixed priority of -2. NMIs cannot be:
  - Masked or prevented from activation by any other exception
  - Preempted by any exception other than Reset.
- **Hard fault**: A hard fault is an exception that occurs because of an error during exception processing, or because an exception cannot be managed by any other exception mechanism. Hard faults have a fixed priority of -1, meaning they have higher priority than any exception with configurable priority.
- **Memory management fault**: A memory management fault is an exception that occurs because of a memory protection related fault. The fixed memory protection constraints determines this fault, for both instruction and data memory transactions. This fault is used to abort instruction accesses to **Execute Never** (XN) memory regions.
Bus fault

A bus fault is an exception that occurs because of a memory related fault for an instruction or data memory transaction. This might be from an error detected on a bus in the memory system.

Usage fault

A usage fault is an exception that occurs because of a fault related to instruction execution. This includes:

- An undefined instruction
- An illegal unaligned access
- Invalid state on instruction execution
- An error on exception return.

The following can cause a usage fault when the core is configured to report them:

- An unaligned address on word and halfword memory access
- Division by zero

SVCall

A supervisor call (SVC) is an exception that is triggered by the SVC instruction. In an OS environment, applications can use SVC instructions to access OS kernel functions and device drivers.

PendSV

PendSV is an interrupt-driven request for system-level service. In an OS environment, use PendSV for context switching when no other exception is active.

SysTick

A SysTick exception is an exception the system timer generates when it reaches zero. Software can also generate a SysTick exception. In an OS environment, the processor can use this exception as system tick.

Interrupt (IRQ)

A interrupt, or IRQ, is an exception signalled by a peripheral, or generated by a software request. All interrupts are asynchronous to instruction execution. In the system, peripherals use interrupts to communicate with the processor.

<td>-</td>
</tr>
</tbody>
</table>
For an asynchronous exception, other than reset, the processor can execute another instruction between when the exception is triggered and when the processor enters the exception handler.

Privileged software can disable the exceptions that Table 16 on page 35 shows as having configurable priority, see:

- System handler control and state register (SCB_SHCSR) on page 139
- Interrupt clear-enable registers (NVIC_ICERx) on page 122

For more information about hard faults, memory management faults, bus faults, and usage faults, see Section 2.4: Fault handling on page 41.

### 2.3.3 Exception handlers

The processor handles exceptions using:

- **Interrupt Service Routines (ISRs)**: Interrupts IRQ0 to IRQ67 are the exceptions handled by ISRs.
- **Fault handlers**: Hard fault, memory management fault, usage fault, bus fault are fault exceptions handled by the fault handlers.
- **System handlers**: NMI, PendSV, SVCall SysTick, and the fault exceptions are all system exceptions that are handled by system handlers.
2.3.4 Vector table

The vector table contains the reset value of the stack pointer, and the start addresses, also called exception vectors, for all exception handlers. Figure 12 on page 37 shows the order of the exception vectors in the vector table. The least-significant bit of each vector must be 1, indicating that the exception handler is Thumb code.

Figure 12. Vector table

</table>

On system reset, the vector table is fixed at address 0x00000000. Privileged software can write to the VTOR to relocate the vector table start address to a different memory location, in the range 0x00000080 to 0x3FFFFF80, see Vector table offset register (SCB_VTOR) on page 133.

2.3.5 Exception priorities

As Table 16 on page 35 shows, all exceptions have an associated priority, with:

- A lower priority value indicating a higher priority
- Configurable priorities for all exceptions except Reset, Hard fault, and NMI.
If software does not configure any priorities, then all exceptions with a configurable priority have a priority of 0. For information about configuring exception priorities see

- System handler priority registers (SHPRx) on page 137
- Interrupt priority registers (NVIC_IPRx) on page 126

Configurable priority values are in the range 0-15. This means that the Reset, Hard fault, and NMI exceptions, with fixed negative priority values, always have higher priority than any other exception.

For example, assigning a higher priority value to IRQ[0] and a lower priority value to IRQ[1] means that IRQ[1] has higher priority than IRQ[0]. If both IRQ[1] and IRQ[0] are asserted, IRQ[1] is processed before IRQ[0].

If multiple pending exceptions have the same priority, the pending exception with the lowest exception number takes precedence. For example, if both IRQ[0] and IRQ[1] are pending and have the same priority, then IRQ[0] is processed before IRQ[1].

When the processor is executing an exception handler, the exception handler is preempted if a higher priority exception occurs. If an exception occurs with the same priority as the exception being handled, the handler is not preempted, irrespective of the exception number. However, the status of the new interrupt changes to pending.

### 2.3.6 Interrupt priority grouping

To increase priority control in systems with interrupts, the NVIC supports priority grouping. This divides each interrupt priority register entry into two fields:

- An upper field that defines the **group priority**
- A lower field that defines a **subpriority** within the group.

Only the group priority determines preemption of interrupt exceptions. When the processor is executing an interrupt exception handler, another interrupt with the same group priority as the interrupt being handled does not preempt the handler.

If multiple pending interrupts have the same group priority, the subpriority field determines the order in which they are processed. If multiple pending interrupts have the same group priority and subpriority, the interrupt with the lowest IRQ number is processed first.

For information about splitting the interrupt priority fields into group priority and subpriority, see Application interrupt and reset control register (SCB_AIRCR) on page 134.

### 2.3.7 Exception entry and return

Descriptions of exception handling use the following terms:

**Preemption**

When the processor is executing an exception handler, an exception can preempt the exception handler if its priority is higher than the priority of the exception being handled. See Section 2.3.6: Interrupt priority grouping for more information about preemption by an interrupt.

When one exception preempts another, the exceptions are called nested exceptions. See Exception entry on page 39 for more information.
Exception entry

Exception entry occurs when there is a pending exception with sufficient priority and either:
- The processor is in Thread mode
- The new exception is of higher priority than the exception being handled, in which case the new exception preempts the original exception.

Sufficient priority means the exception has more priority than any limits set by the mask registers, see Exception mask registers on page 20. An exception with less priority than this is pending but is not handled by the processor.

When the processor takes an exception, unless the exception is a tail-chained or a late-arriving exception, the processor pushes information onto the current stack. This operation is referred as stacking and the structure of eight data words is referred as stack frame. The stack frame contains the following information:
- R0-R3, R12
- Return address
- PSR
- LR.

Immediately after stacking, the stack pointer indicates the lowest address in the stack frame. Unless stack alignment is disabled, the stack frame is aligned to a double-word address. If the STKALIGN bit of the Configuration Control Register (CCR) is set to 1, stack align adjustment is performed during stacking.

Return

This occurs when the exception handler is completed, and:
- There is no pending exception with sufficient priority to be serviced
- The completed exception handler was not handling a late-arriving exception.

The processor pops the stack and restores the processor state to the state it had before the interrupt occurred. See Exception return on page 40 for more information.

Tail-chaining

This mechanism speeds up exception servicing. On completion of an exception handler, if there is a pending exception that meets the requirements for exception entry, the stack pop is skipped and control transfers to the new exception handler.

Late-arriving

This mechanism speeds up preemption. If a higher priority exception occurs during state saving for a previous exception, the processor switches to handle the higher priority exception and initiates the vector fetch for that exception. State saving is not affected by late arrival because the state saved is the same for both exceptions. Therefore the state saving continues uninterrupted. The processor can accept a late arriving exception until the first instruction of the exception handler of the original exception enters the execute stage of the processor. On return from the exception handler of the late-arriving exception, the normal tail-chaining rules apply.
The stack frame includes the return address. This is the address of the next instruction in the interrupted program. This value is restored to the PC at exception return so that the interrupted program resumes.

In parallel to the stacking operation, the processor performs a vector fetch that reads the exception handler start address from the vector table. When stacking is complete, the processor starts executing the exception handler. At the same time, the processor writes an EXC_RETURN value to the LR. This indicates which stack pointer corresponds to the stack frame and what operation mode the processor was in before the entry occurred.

If no higher priority exception occurs during exception entry, the processor starts executing the exception handler and automatically changes the status of the corresponding pending interrupt to active.

If another higher priority exception occurs during exception entry, the processor starts executing the exception handler for this exception and does not change the pending status of the earlier exception. This is the late arrival case.

**Exception return**

Exception return occurs when the processor is in Handler mode and executes one of the following instructions to load the EXC_RETURN value into the PC:

- A POP instruction that includes the PC
- A BX instruction with any register.
- An LDR or LDM instruction with the PC as the destination

EXC_RETURN is the value loaded into the LR on exception entry. The exception mechanism relies on this value to detect when the processor has completed an exception handler. The lowest four bits of this value provide information on the return stack and processor mode. Table 17 shows the EXC_RETURN[3:0] values with a description of the exception return behavior.

The processor sets EXC_RETURN bits[31:4] to 0xFFFFFFF. When this value is loaded into the PC it indicates to the processor that the exception is complete, and the processor initiates the exception return sequence.

**Table 17. Exception return behavior**

| 0b1001          | Return to Thread mode.  
Exception return gets state from MSP.  
Execution uses MSP after return. |
2.4 Fault handling

Faults are a subset of the exceptions, see Exception model on page 34. The following generate a fault:

- A bus error on:
  - An instruction fetch or vector table load
  - A data access
- An internally-detected error such as an undefined instruction or an attempt to change state with a BX instruction
- Attempting to execute an instruction from a memory region marked as Non-Executable (XN).

2.4.1 Fault types

*Table 18* shows the types of fault, the handler used for the fault, the corresponding fault status register, and the register bit that indicates that the fault has occurred. See Configurable fault status register (SCB_CFSR) on page 141 for more information about the fault status registers.

<table>

</tbody>
</table>
2.4.2 Fault escalation and hard faults

All faults exceptions except for hard fault have configurable exception priority, see System handler priority registers (SHPRx) on page 137. Software can disable execution of the handlers for these faults, see System handler control and state register (SCB_SHCSR) on page 139.

Usually, the exception priority, together with the values of the exception mask registers, determines whether the processor enters the fault handler, and whether a fault handler can preempt another fault handler. as described in Section 2.3: Exception model on page 34.

In some situations, a fault with configurable priority is treated as a hard fault. This is called priority escalation, and the fault is described as escalated to hard fault. Escalation to hard fault occurs when:

- A fault handler causes the same kind of fault as the one it is servicing. This escalation to hard fault occurs because a fault handler cannot preempt itself because it must have the same priority as the current priority level.
- A fault handler causes a fault with the same or lower priority as the fault it is servicing. This is because the handler for the new fault cannot preempt the currently executing fault handler.
- An exception handler causes a fault for which the priority is the same as or lower than the currently executing exception.
- A fault occurs and the handler for that fault is not enabled.

If a bus fault occurs during a stack push when entering a bus fault handler, the bus fault does not escalate to a hard fault. This means that if a corrupted stack causes a fault, the fault handler executes even though the stack push for the handler failed. The fault handler operates but the stack contents are corrupted.

Only Reset and NMI can preempt the fixed priority hard fault. A hard fault can preempt any exception other than Reset, NMI, or another hard fault.
2.4.3 Fault status registers and fault address registers

The fault status registers indicate the cause of a fault. For bus faults and memory management faults, the fault address register indicates the address accessed by the operation that caused the fault, as shown in Table 19.

Table 19. Fault status and fault address registers

<td>UFSR</td>
<td>-</td>
<td>Configurable fault status register (SCB_CFSR) on page 141</td>
</tr>
</tbody>
</table>

2.4.4 Lockup

The processor enters a lockup state if a hard fault occurs when executing the NMI or hard fault handlers. When the processor is in lockup state it does not execute any instructions. The processor remains in lockup state until either:

- It is reset
- An NMI occurs

If lockup state occurs from the NMI handler a subsequent NMI does not cause the processor to leave lockup state.

2.5 Power management

The STM32 and Cortex-M3 processor sleep modes reduce power consumption:

- Sleep mode stops the processor clock. All other system and peripheral clocks may still be running.
- Deep sleep mode stops most of the STM32 system and peripheral clocks. At product level, this corresponds to either the Stop or the Standby mode. For more details, please refer to the “Power modes” Section in the STM32 reference manual.

The SLEEPDEEP bit of the SCR selects which sleep mode is used, see System control register (SCB_SCR) on page 135. For more information about the behavior of the sleep modes see the STM32 product reference manual.

This section describes the mechanisms for entering sleep mode, and the conditions for waking up from sleep mode.
2.5.1 Entering sleep mode

This section describes the mechanisms software can use to put the processor into sleep mode.

The system can generate spurious wakeup events, for example a debug operation wakes up the processor. Therefore software must be able to put the processor back into sleep mode after such an event. A program might have an idle loop to put the processor back to sleep mode.

Wait for interrupt

The wait for interrupt instruction, WFI, causes immediate entry to sleep mode. When the processor executes a WFI instruction it stops executing instructions and enters sleep mode. See WFI on page 105 for more information.

Wait for event

The wait for event instruction, WFE, causes entry to sleep mode conditional on the value of an one-bit event register. When the processor executes a WFE instruction, it checks this register:

- If the register is 0 the processor stops executing instructions and enters sleep mode
- If the register is 1 the processor clears the register to 0 and continues executing instructions without entering sleep mode.

See WFE on page 104 for more information.

If the event register is 1, this indicate that the processor must not enter sleep mode on execution of a WFE instruction. Typically, this is because an external event signal is asserted, or a processor in the system has executed an SEV instruction, see SEV on page 103. Software cannot access this register directly.

Sleep-on-exit

If the SLEEPONEXIT bit of the SCR is set to 1, when the processor completes the execution of an exception handler it returns to Thread mode and immediately enters sleep mode. Use this mechanism in applications that only require the processor to run when an exception occurs.

2.5.2 Wakeup from sleep mode

The conditions for the processor to wakeup depend on the mechanism that cause it to enter sleep mode.

Wakeup from WFI or sleep-on-exit

Normally, the processor wakes up only when it detects an exception with sufficient priority to cause exception entry.

Some embedded systems might have to execute system restore tasks after the processor wakes up, and before it executes an interrupt handler. To achieve this set the PRIMASK bit to 1 and the FAULTMASK bit to 0. If an interrupt arrives that is enabled and has a higher priority than current exception priority, the processor wakes up but does not execute the interrupt handler until the processor sets PRIMASK to zero. For more information about PRIMASK and FAULTMASK see Exception mask registers on page 20.
Wakeup from WFE

The processor wakes up if:

- it detects an exception with sufficient priority to cause exception entry
- it detects an external event signal, see *The external event input* on page 45

In addition, if the SEVONPEND bit in the SCR is set to 1, any new pending interrupt triggers an event and wakes up the processor, even if the interrupt is disabled or has insufficient priority to cause exception entry. For more information about the SCR see *System control register (SCB_SCR)* on page 135.

2.5.3 The external event input

The processor provides an external event input signal. This signal can be generated by the up to 16 external input lines, by the PVD, RTC alarm or by the USB wakeup event, configured through the external interrupt/event controller (EXTI).

This signal can wakeup the processor from WFE, or set the internal WFE event register to one to indicate that the processor must not enter sleep mode on a later WFE instruction, see *Wait for event* on page 44. For more details please refer to the STM32 reference manual, section 4.3 Low power modes.

2.5.4 Power management programming hints

ANSI C cannot directly generate the WFI and WFE instructions. The CMSIS provides the following intrinsic functions for these instructions:

```c
void __WFE(void) // Wait for Event
void __WFE(void) // Wait for Interrupt
```
3 The Cortex-M3 instruction set

3.1 Instruction set summary

The processor implements a version of the thumb instruction set. Table 20 lists the supported instructions.

In Table 20:
- Angle brackets, <>, enclose alternative forms of the operand
- Braces, {}, enclose optional operands
- The operands column is not exhaustive
- Op2 is a flexible second operand that can be either a register or a constant
- Most instructions can use an optional condition code suffix

For more information on the instructions and operands, see the instruction descriptions.

3.2 Intrinsic functions

ANSI cannot directly access some Cortex-M3 instructions. This section describes intrinsic functions that can generate these instructions, provided by the CMIS and that might be provided by a C compiler. If a C compiler does not support an appropriate intrinsic function, you might have to use an inline assembler to access some instructions.

The CMSIS provides the intrinsic functions listed in Table 21 to generate instructions that ANSI cannot directly access.

### 3.3 About the instruction descriptions

The following sections give more information about using the instructions:

- [Operands on page 52](#)
- [Restrictions when using PC or SP on page 53](#)
- [Flexible second operand on page 53](#)
- [Shift operations on page 54](#)
- [Address alignment on page 57](#)
- [PC-relative expressions on page 57](#)
- [Conditional execution on page 58](#)
- [Instruction width selection on page 60](#)

#### 3.3.1 Operands

An instruction operand can be an ARM register, a constant, or another instruction-specific parameter. Instructions act on the operands and often store the result in a destination register. When there is a destination register in the instruction, it is usually specified before the operands.

Operands in some instructions are flexible in that they can either be a register or a constant (see [Flexible second operand](#)).
3.3.2 Restrictions when using PC or SP

Many instructions have restrictions on whether you can use the program counter (PC) or stack pointer (SP) for the operands or destination register. See instruction descriptions for more information.

Bit[0] of any address written to the PC with a BX, BLX, LDM, LDR, or POP instruction must be 1 for correct execution, because this bit indicates the required instruction set, and the Cortex-M3 processor only supports thumb instructions.

3.3.3 Flexible second operand

Many general data processing instructions have a flexible second operand. This is shown as operand2 in the descriptions of the syntax of each instruction.

Operand2 can be a:

- Constant
- Register with optional shift

Constant

You specify an operand2 constant in the form #constant, where constant can be:

- Any constant that can be produced by shifting an 8-bit value left by any number of bits within a 32-bit word.
- Any constant of the form 0x00XY00XY
- Any constant of the form 0xXY00XY00
- Any constant of the form 0xXYXYXYXY

In the constants shown above, X and Y are hexadecimal digits.

In addition, in a small number of instructions, constant can take a wider range of values. These are described in the individual instruction descriptions.

When an operand2 constant is used with the instructions MOVS, MVNS, ANDS, ORRS, ORNS, EORS, BICS, TEQ or TST, the carry flag is updated to bit[31] of the constant, if the constant is greater than 255 and can be produced by shifting an 8-bit value. These instructions do not affect the carry flag if operand2 is any other constant.

Instruction substitution

Your assembler might be able to produce an equivalent instruction in cases where you specify a constant that is not permitted. For example, an assembler might assemble the instruction CMP Rd, #0xFFFFFFFF as the equivalent instruction CMN Rd, #0x2.
Register with optional shift

An operand2 register is specified in the form $Rm_{( shift)}$, where:

- $Rm$ is the register holding the data for the second operand
- $Shift$ is an optional shift to be applied to $Rm$. It can be one of:
  - ASR #$n$: Arithmetic shift right $n$ bits, $1 \leq n \leq 32$
  - LSL #$n$: Logical shift left $n$ bits, $1 \leq n \leq 31$
  - LSR #$n$: Logical shift right $n$ bits, $1 \leq n \leq 32$
  - ROR #$n$: Rotate right $n$ bits, $1 \leq n \leq 31$
  - RRX: Rotate right one bit, with extend
  —: If omitted, no shift occurs, equivalent to LSL #0

If you omit the shift, or specify LSL #0, the instruction uses the value in $Rm$.

If you specify a shift, the shift is applied to the value in $Rm$, and the resulting 32-bit value is used by the instruction. However, the contents in the register $Rm$ remains unchanged. Specifying a register with shift also updates the carry flag when used with certain instructions. For information on the shift operations and how they affect the carry flag, see Shift operations.

3.3.4 Shift operations

Register shift operations move the bits in a register left or right by a specified number of bits, the shift length. Register shift can be performed:

- Directly by the instructions ASR, LSR, LSL, ROR, and RRX. The result is written to a destination register.
- During the calculation of operand2 by the instructions that specify the second operand as a register with shift (see Flexible second operand on page 53). The result is used by the instruction.

The permitted shift lengths depend on the shift type and the instruction (see the individual instruction description or Flexible second operand). If the shift length is 0, no shift occurs. Register shift operations update the carry flag except when the specified shift length is 0. The following sub-sections describe the various shift operations and how they affect the carry flag. In these descriptions, $Rm$ is the register containing the value to be shifted, and $n$ is the shift length.

ASR

Arithmetic shift right by $n$ bits moves the left-hand $32-n$ bits of the register $Rm$, to the right by $n$ places, into the right-hand $32-n$ bits of the result. And it copies the original bit[31] of the register into the left-hand $n$ bits of the result (see Figure 13: ASR#3 on page 55).

You can use the ASR #$n$ operation to divide the value in the register $Rm$ by $2^n$, with the result being rounded towards negative-infinity.

When the instruction is ASRS or when ASR #$n$ is used in operand2 with the instructions MOV$S$, MVNS, ANDS, ORRS, ORNS, EORS, BICS, TEQ or TST, the carry flag is updated to the last bit shifted out, bit$[n-1]$, of the register $Rm$.

Note:
1. If $n$ is 32 or more, all the bits in the result are set to the value of bit[31] of $Rm$.
2. If $n$ is 32 or more and the carry flag is updated, it is updated to the value of bit[31] of $Rm$.
Logical shift right by \( n \) bits moves the left-hand 32-\( n \) bits of the register \( Rm \), to the right by \( n \) places, into the right-hand 32-\( n \) bits of the result. And it sets the left-hand \( n \) bits of the result to 0 (see Figure 14).

You can use the LSR \#n operation to divide the value in the register \( Rm \) by \( 2^n \), if the value is regarded as an unsigned integer.

When the instruction is LSRS or when LSR \#n is used in operand2 with the instructions MOV, MVNS, AND, ORRS, ORNS, EORS, BICS, TEQ or TST, the carry flag is updated to the last bit shifted out, bit[\( n-1 \)], of the register \( Rm \).

Note:
1. If \( n \) is 32 or more, then all the bits in the result are cleared to 0.
2. If \( n \) is 33 or more and the carry flag is updated, it is updated to 0.

Logical shift left by \( n \) bits moves the right-hand 32-\( n \) bits of the register \( Rm \), to the left by \( n \) places, into the left-hand 32-\( n \) bits of the result. And it sets the right-hand \( n \) bits of the result to 0 (see Figure 15: LSL\#3 on page 56).

You can use the LSL \#n operation to multiply the value in the register \( Rm \) by \( 2^n \), if the value is regarded as an unsigned integer or a two's complement signed integer. Overflow can occur without warning.

When the instruction is LSLS or when LSL \#n, with non-zero \( n \), is used in operand2 with the instructions MOV, MVNS, AND, ORRS, ORNS, EORS, BICS, TEQ or TST, the carry flag is updated to the last bit shifted out, bit[32-\( n \)], of the register \( Rm \). These instructions do not affect the carry flag when used with LSL \#0.

Note:
1. If \( n \) is 32 or more, then all the bits in the result are cleared to 0.
2. If \( n \) is 33 or more and the carry flag is updated, it is updated to 0.
ROR

Rotate right by \( n \) bits moves the left-hand 32-\( n \) bits of the register \( Rm \), to the right by \( n \) places, into the right-hand 32-\( n \) bits of the result. It also moves the right-hand \( n \) bits of the register into the left-hand \( n \) bits of the result (see Figure 16).

When the instruction is RORS or when ROR \( \#n \) is used in operand2 with the instructions MOVS, MVNS, ANDS, ORRS, ORNS, EORS, BICS, TEQ or TST, the carry flag is updated to the last bit rotation, bit[\( n-1 \)], of the register \( Rm \).

Note:
1. If \( n \) is 32, then the value of the result is same as the value in \( Rm \), and if the carry flag is updated, it is updated to bit[31] of \( Rm \).
2. ROR with shift length, \( n \), more than 32 is the same as ROR with shift length \( n-32 \).

RRX

Rotate right with extend moves the bits of the register \( Rm \) to the right by one bit. And it copies the carry flag into bit[31] of the result (see Figure 17).

When the instruction is RRXS or when RRX is used in operand2 with the instructions MOVS, MVNS, ANDS, ORRS, ORNS, EORS, BICS, TEQ or TST, the carry flag is updated to bit[0] of the register \( Rm \).
3.3.5 Address alignment

An aligned access is an operation where a word-aligned address is used for a word, dual word, or multiple word access, or where a halfword-aligned address is used for a halfword access. Byte accesses are always aligned.

The Cortex-M3 processor supports unaligned access only for the following instructions:

- LDR, LDRT
- LDRH, LDRHT
- LDRSH, LDRSHT
- STR, STRT
- STRH, STRHT

All other load and store instructions generate a usage fault exception if they perform an unaligned access, and therefore their accesses must be address aligned. For more information about usage faults see Fault handling on page 41.

Unaligned accesses are usually slower than aligned accesses. In addition, some memory regions might not support unaligned accesses. Therefore, ARM recommends that programmers ensure that accesses are aligned. To avoid accidental generation of unaligned accesses, use the UNALIGN_TRP bit in the configuration and control register to trap all unaligned accesses, see Configuration and control register (SCB_CCR) on page 136.

3.3.6 PC-relative expressions

A PC-relative expression or label is a symbol that represents the address of an instruction or literal data. It is represented in the instruction as the PC value plus or minus a numeric offset. The assembler calculates the required offset from the label and the address of the current instruction. If the offset is too big, the assembler produces an error.

- For the B, BL, CBNZ, and CBZ instructions, the value of the PC is the address of the current instruction plus four bytes.
- For all other instructions that use labels, the value of the PC is the address of the current instruction plus four bytes, with bit[1] of the result cleared to 0 to make it word-aligned.
- Your assembler might permit other syntaxes for PC-relative expressions, such as a label plus or minus a number, or an expression of the form [PC, #number].
3.3.7 Conditional execution

Most data processing instructions can optionally update the condition flags in the application program status register (APSR) according to the result of the operation (see Application program status register on page 18). Some instructions update all flags, and some only update a subset. If a flag is not updated, the original value is preserved. See the instruction descriptions for the flags they affect.

You can execute an instruction conditionally, based on the condition flags set in another instruction:

- Immediately after the instruction that updated the flags
- After any number of intervening instructions that have not updated the flags

Conditional execution is available by using conditional branches or by adding condition code suffixes to instructions. See Table 23: Condition code suffixes on page 59 for a list of the suffixes to add to instructions to make them conditional instructions. The condition code suffix enables the processor to test a condition based on the flags. If the condition test of a conditional instruction fails, the instruction:

- Does not execute
- Does not write any value to its destination register
- Does not affect any of the flags
- Does not generate any exception

Conditional instructions, except for conditional branches, must be inside an If-then instruction block. See IT on page 95 for more information and restrictions when using the IT instruction. Depending on the vendor, the assembler might automatically insert an IT instruction if you have conditional instructions outside the IT block.

Use the CBZ and CBNZ instructions to compare the value of a register against zero and branch on the result.

This section describes:

- The condition flags
- Condition code suffixes on page 59

The condition flags

The APSR contains the following condition flags:

- N: Set to 1 when the result of the operation is negative, otherwise cleared to 0
- Z: Set to 1 when the result of the operation is zero, otherwise cleared to 0
- C: Set to 1 when the operation results in a carry, otherwise cleared to 0.
- V: Set to 1 when the operation causes an overflow, otherwise cleared to 0.

For more information about the APSR see Program status register on page 17.

A carry occurs:

- If the result of an addition is greater than or equal to \(2^{32}\)
- If the result of a subtraction is positive or zero
- As the result of an inline barrel shifter operation in a move or logical instruction

Overflow occurs if the result of an add, subtract, or compare is greater than or equal to \(2^{31}\), or less than \(-2^{31}\).
Most instructions update the status flags only if the S suffix is specified. See the instruction
descriptions for more information.

**Condition code suffixes**

The instructions that can be conditional have an optional condition code, shown in syntax
descriptions as `{cond}`. Conditional execution requires a preceding IT instruction. An
instruction with a condition code is only executed if the condition code flags in the APSR
meet the specified condition. **Table 23** shows the condition codes to use.

You can use conditional execution with the IT instruction to reduce the number of branch
instructions in code. **Table 23** also shows the relationship between condition code suffixes and the N, Z, C, and V
flags.

**Table 23. Condition code suffixes**

<table>
<thead>
<tr>
<th>Suffix</th>

**Specific example 1: Absolute value** shows the use of a conditional instruction to find the
absolute value of a number. R0 = ABS(R1).

**Specific example 1: Absolute value**

MOVSR0, R1; R0 = R1, setting flags
IT MI; IT instruction for the negative condition
RSBMIR0, R1, #0; If negative, R0 = -R1
Specific example 2: Compare and update value shows the use of conditional instructions to update the value of R4 if the signed value R0 and R2 are greater than R1 and R3 respectively.

Specific example 2: Compare and update value

CMP R0, R1 ; compare R0 and R1, setting flags
ITT GT ; IT instruction for the two GT conditions
CMPGT R2, R3; if 'greater than', compare R2 and R3, setting flags
MOVGT R4, R5 ; if still 'greater than', do R4 = R5

3.3.8 Instruction width selection

There are many instructions that can generate either a 16-bit encoding or a 32-bit encoding depending on the operands and destination register specified. For some of these instructions, you can force a specific instruction size by using an instruction width suffix. The .W suffix forces a 32-bit instruction encoding. The .N suffix forces a 16-bit instruction encoding.

If you specify an instruction width suffix and the assembler cannot generate an instruction encoding of the requested width, it generates an error.

In some cases it might be necessary to specify the .W suffix, for example if the operand is the label of an instruction or literal data, as in the case of branch instructions. This is because the assembler might not automatically generate the right size encoding.

To use an instruction width suffix, place it immediately after the instruction mnemonic and condition code, if any. Specific example 3: Instruction width selection shows instructions with the instruction width suffix.

Specific example 3: Instruction width selection

BCS.W label; creates a 32-bit instruction even for a short branch
ADDS.W R0, R0, R1; creates a 32-bit instruction even though the same operation can be done by a 16-bit instruction
3.4 Memory access instructions

Table 24 shows the memory access instructions:

</tbody>
</table>

3.4.1 ADR

Load PC-relative address.

Syntax

ADR(cond) Rd, label

where:

- `cond` is an optional condition code (see Conditional execution on page 58)
- `Rd` is the destination register
- `label` is a PC-relative expression (see PC-relative expressions on page 57)

Operation

ADR determines the address by adding an immediate value to the PC. It writes the result to the destination register.

ADR produces position-independent code, because the address is PC-relative.

If you use ADR to generate a target address for a BX or BLX instruction, you must ensure that bit[0] of the address you generate is set to 1 for correct execution.

Values of `label` must be within the range -4095 to 4095 from the address in the PC.
Note: You might have to use the .W suffix to get the maximum offset range or to generate addresses that are not word-aligned (see Instruction width selection on page 60).

Restrictions

Rd must be neither SP nor PC.

Condition flags

This instruction does not change the flags.

Examples

ADR R1, TextMessage; write address value of a location labelled as TextMessage to R1

3.4.2 LDR and STR, immediate offset

Load and store with immediate offset, pre-indexed immediate offset, or post-indexed immediate offset.

Syntax

op{type}{cond} Rt, [Rn , #offset]; immediate offset
op{type}{cond} Rt, [Rn, #offset]!; pre-indexed
op{type}{cond} Rt, [Rn], #offset; post-indexed
opD{cond} Rt, Rt2, [Rn , #offset]]; immediate offset, two words
opD{cond} Rt, Rt2, [Rn, #offset]!; pre-indexed, two words
opD{cond} Rt, Rt2, [Rn], #offset; post-indexed, two words

where:

- ‘op’ is either LDR (load register) or STR (store register)
- ‘type’ is one of the following:
  - B: Unsigned byte, zero extends to 32 bits on loads
  - SB: Signed byte, sign extends to 32 bits (LDR only)
  - H: Unsigned halfword, zero extends to 32 bits on loads
  - SH: Signed halfword, sign extends to 32 bits (LDR only)
  - —: Omit, for word
- ‘cond’ is an optional condition code (see Conditional execution on page 56)
- ‘Rt’ is the register to load or store
- ‘Rn’ is the register on which the memory address is based
- ‘offset’ is an offset from Rn. If offset is omitted, the address is the contents of Rn
- ‘Rt2’ is the additional register to load or store for two-word operations
Operation

LDR instructions load one or two registers with a value from memory. STR instructions store one or two register values to memory.

Load and store instructions with immediate offset can use the following addressing modes:

- **Offset addressing**
  The offset value is added to or subtracted from the address obtained from the register \( Rn \). The result is used as the address for the memory access. The register \( Rn \) is unaltered. The assembly language syntax for this mode is: \([Rn, \#\text{offset}]\).

- **Pre-indexed addressing**
  The offset value is added to or subtracted from the address obtained from the register \( Rn \). The result is used as the address for the memory access and written back into the register \( Rn \). The assembly language syntax for this mode is: \([Rn, \#\text{offset}]\).

- **Post-indexed addressing**
  The address obtained from the register \( Rn \) is used as the address for the memory access. The offset value is added to or subtracted from the address, and written back into the register \( Rn \). The assembly language syntax for this mode is: \([Rn, \#\text{offset}]\).

The value to load or store can be a byte, halfword, word, or two words. Bytes and halfwords can either be signed or unsigned (see *Address alignment on page 57*).

*Table 25* shows the range of offsets for immediate, pre-indexed and post-indexed forms.

**Table 25. Immediate, pre-indexed and post-indexed offset ranges**

<table>
<thead>
<tr>
<th>Instruction type</th>
<th>Immediate offset</th>
<th>Pre-indexed</th>
<th>Post-indexed</th>
</tr>
</thead>
<tbody>
<tr>
<td>Word, halfword, signed halfword, byte, or signed byte</td>
<td>-255 to 4095</td>
<td>-255 to 255</td>
<td>-255 to 255</td>
</tr>
<tr>
<td>Two words</td>
<td>Multiple of 4 in the range -1020 to 1020</td>
<td>Multiple of 4 in the range -1020 to 1020</td>
<td>Multiple of 4 in the range -1020 to 1020</td>
</tr>
</tbody>
</table>

Restrictions

- **For load instructions**
  - \( Rt \) can be SP or PC for word loads only
  - \( Rt \) must be different from \( Rt2 \) for two-word loads
  - \( Rn \) must be different from \( Rt \) and \( Rt2 \) in the pre-indexed or post-indexed forms

- **When \( Rt \) is PC in a word load instruction**
  - bit[0] of the loaded value must be 1 for correct execution
  - A branch occurs to the address created by changing bit[0] of the loaded value to 0
  - If the instruction is conditional, it must be the last instruction in the IT block

- **For store instructions**
  - \( Rt \) can be SP for word stores only
  - \( Rt \) must not be PC
  - \( Rn \) must not be PC
  - \( Rn \) must be different from \( Rt \) and \( Rt2 \) in the pre-indexed or post-indexed forms
Condition flags

These instructions do not change the flags.

Examples

LDRR8, [R10]; loads R8 from the address in R10.
LDRNER2, [R5, #960]!!; loads (conditionally) R2 from a word
; 960 bytes above the address in R5, and
; increments R5 by 960.
STRR2, [R9, #const-struc]; const-struc is an expression evaluating
; to a constant in the range 0-4095.
STRHR3, [R4], #4; Store R3 as halfword data into address in
; R4, then increment R4 by 4
LDRD R8, R9, [R3, #0x20]; Load R8 from a word 32 bytes above the
; address in R3, and load R9 from a word 36
; bytes above the address in R3
STRDR0, R1, [R8], #4; Store R0 to address in R8, and store R1 to
; a word 4 bytes above the address in R8,
; and then decrement R8 by 16.

3.4.3 LDR and STR, register offset

Load and store with register offset.

Syntax

op{type}{cond} Rt, [Rn, Rm {, LSL #n}]  

where:

● ‘op’ is either LDR (load register) or STR (store register)
● ‘type’ is one of the following:
  B: Unsigned byte, zero extends to 32 bits on loads
  SB: Signed byte, sign extends to 32 bits (LDR only)
  H: Unsigned halfword, zero extends to 32 bits on loads
  SH: Signed halfword, sign extends to 32 bits (LDR only)
  —: Omit, for word
● ‘cond’ is an optional condition code (see Conditional execution on page 58)
● ‘Rt’ is the register to load or store
● ‘Rn’ is the register on which the memory address is based
● ‘Rm’ is a register containing a value to be used as the offset
● ‘LSL #n’ is an optional shift, with n in the range 0 to 3

Operation

LDR instructions load a register with a value from memory. STR instructions store a register value into memory.

The memory address to load from or store to is at an offset from the register Rn. The offset is specified by the register Rm and can be shifted left by up to 3 bits using LSL.

The value to load or store can be a byte, halfword, or word. For load instructions, bytes and halfwords can either be signed or unsigned (see Address alignment on page 57).
Restrictions
In these instructions:

- **Rn** must not be PC
- **Rm** must be neither SP nor PC
- **Rt** can be SP only for word loads and word stores
- **Rt** can be PC only for word loads

When **Rt** is PC in a word load instruction:

- bit[0] of the loaded value must be 1 for correct execution, and a branch occurs to this halfword-aligned address
- If the instruction is conditional, it must be the last instruction in the IT block.

Condition flags
These instructions do not change the flags.

Examples

```
STRR0, [R5, R1]; store value of R0 into an address equal to
; sum of R5 and R1
LDRSBR0, [R5, R1, LSL #1]; read byte value from an address equal to
; sum of R5 and two times R1, sign extended it
; to a word value and put it in R0
STRR0, [R1, R2, LSL #2]; stores R0 to an address equal to sum of R1
; and four times R2
```

3.4.4 LDR and STR, unprivileged
Load and store with unprivileged access.

Syntax

```
op{type}T{cond} Rt, [Rn {, #offset}]; immediate offset
```

where:

- ‘**op**’ is either LDR (load register) or STR (store register)
- ‘**type**’ is one of the following:
  - B: Unsigned byte, zero extends to 32 bits on loads
  - SB: Signed byte, sign extends to 32 bits (LDR only)
  - H: Unsigned halfword, zero extends to 32 bits on loads
  - SH: Signed halfword, sign extends to 32 bits (LDR only)
  - -: Omit, for word
- ‘**cond**’ is an optional condition code (see Conditional execution on page 58)
- ‘**Rt**’ is the register to load or store
- ‘**Rn**’ is the register on which the memory address is based
- ‘**offset**’ is an offset from **Rn** and can be 0 to 255. If **offset** is omitted, the address is the value in **Rn**.
Operation

These load and store instructions perform the same function as the memory access instructions with immediate offset (see LDR and STR, immediate offset on page 62). The difference is that these instructions have only unprivileged access even when used in privileged software.

When used in unprivileged software, these instructions behave in exactly the same way as normal memory access instructions with immediate offset.

Restrictions

In these instructions:
- \( Rn \) must not be PC
- \( Rt \) must be neither SP nor PC.

Condition flags

These instructions do not change the flags.

Examples

\[
\text{STRBTEQR4, [R7]; conditionally store least significant byte in }
\]

\[
\text{LDRHTR2, [R2, #8]; load halfword value from an address equal to}
\]

\[
\text{; sum of R2 and 8 into R2, with unprivileged access}
\]

3.4.5 LDR, PC-relative

Load register from memory.

Syntax

\[
\text{LDR(type)(cond) Rt, label}
\]

\[
\text{LDRD(cond) Rt, Rt2, label; load two words}
\]

where:
- ‘type’ is one of the following:
  - B: Unsigned byte, zero extends to 32 bits
  - SB: Signed byte, sign extends to 32 bits
  - H: Unsigned halfword, sign extends to 32 bits
  - SH: Signed halfword, sign extends to 32 bits
  - : Omit, for word
- ‘cond’ is an optional condition code (see Conditional execution on page 58)
- ‘Rt’ is the register to load or store
- ‘Rt2’ is the second register to load or store
- ‘label’ is a PC-relative expression (see PC-relative expressions on page 57)
Operation

LDR loads a register with a value from a PC-relative memory address. The memory address is specified by a label or by an offset from the PC.

The value to load or store can be a byte, halfword, or word. For load instructions, bytes and halfwords can either be signed or unsigned (see Address alignment on page 57).

'label' must be within a limited range of the current instruction. Table 26 shows the possible offsets between label and the PC.

Table 26. label-PC offset ranges

<table>
<thead>
<tr>
<th>Instruction type</th>
<th>Offset range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Word, halfword, signed halfword, byte, signed byte</td>
<td>-4095 to 4095</td>
</tr>
<tr>
<td>Two words</td>
<td>-1020 to 1020</td>
</tr>
</tbody>
</table>

You might have to use the .W suffix to get the maximum offset range (see Instruction width selection on page 60).

Restrictions

In these instructions:

- $Rt$ can be SP or PC only for word loads
- $Rt2$ must be neither SP nor PC
- $Rt$ must be different from $Rt2$

When $Rt$ is PC in a word load instruction:

- bit[0] of the loaded value must be 1 for correct execution, and a branch occurs to this halfword-aligned address
- If the instruction is conditional, it must be the last instruction in the IT block.

Condition flags

These instructions do not change the flags.

Examples

LDR R0, LookUpTable; load R0 with a word of data from an address
; labelled as LookUpTable
LDRS R7, localdata; load a byte value from an address labelled
; as localdata, sign extend it to a word
; value, and put it in R7
3.4.6 LDM and STM

Load and store multiple registers.

Syntax

\[ \text{op}\{\text{addr\_mode}\}{\text{cond}} \ Rn\{!\}, \ \text{reglist} \]

where:

- ‘\text{op}’ is either LDM (load multiple register) or STM (store multiple register)
- ‘\text{addr\_mode}’ is any of the following:
  - IA: Increment address after each access (this is the default)
  - DB: Decrement address before each access
- ‘\text{cond}’ is an optional condition code (see Conditional execution on page 58)
- ‘\text{Rn}’ is the register on which the memory addresses are based
- ‘!’ is an optional writeback suffix. If ! is present, the final address that is loaded from or stored to is written back into \(Rn\).
- ‘\text{reglist}’ is a list of one or more registers to be loaded or stored, enclosed in braces. It can contain register ranges. It must be comma-separated if it contains more than one register or register range (see Examples on page 69).

LDM and LDMFD are synonyms for LDMIA. LDMFD refers to its use for popping data from full descending stacks.

LDMEA is a synonym for LDMDB, and refers to its use for popping data from empty ascending stacks.

STM and STMEA are synonyms for STMIA. STMEA refers to its use for pushing data onto empty ascending stacks.

STMFD is a synonym for STMDB, and refers to its use for pushing data onto full descending stacks.

Operation

LDM instructions load the registers in \(\text{reglist}\) with word values from memory addresses based on \(Rn\).

STM instructions store the word values in the registers in \(\text{reglist}\) to memory addresses based on \(Rn\).

For LDM, LDMIA, LDMFD, STM, STMIA, and STMEA the memory addresses used for the accesses are at 4-byte intervals ranging from \(Rn\) to \(Rn + 4 \times (n-1)\), where \(n\) is the number of registers in \(\text{reglist}\). The accesses happen in order of increasing register numbers, with the lowest numbered register using the lowest memory address and the highest number register using the highest memory address. If the writeback suffix is specified, the value \(Rn + 4 \times (n-1)\) is written back to \(Rn\).

For LDMDB, LDMEA, STMDB, and STMFD the memory addresses used for the accesses are at 4-byte intervals ranging from \(Rn\) to \(Rn - 4 \times (n-1)\), where \(n\) is the number of registers in \(\text{reglist}\). The accesses happen in order of decreasing register numbers, with the highest numbered register using the highest memory address and the lowest number register using the lowest memory address. If the writeback suffix is specified, the value \(Rn - 4 \times (n-1)\) is written back to \(Rn\).
The PUSH and POP instructions can be expressed in this form (see *PUSH and POP* for details).

**Restrictions**

In these instructions:
- \( Rn \) must not be PC
- \( \text{reglist} \) must not contain SP
- In any STM instruction, \( \text{reglist} \) must not contain PC
- In any LDM instruction, \( \text{reglist} \) must not contain PC if it contains LR
- \( \text{reglist} \) must not contain \( Rn \) if you specify the writeback suffix

When PC is in \( \text{reglist} \) in an LDM instruction:
- bit[0] of the value loaded to the PC must be 1 for correct execution, and a branch occurs to this halfword-aligned address.
- If the instruction is conditional, it must be the last instruction in the IT block

**Condition flags**

These instructions do not change the flags.

**Examples**

```
LDMR8,(R0,R2,R9); LDMIA is a synonym for LDM
STMDBR1!,{R3-R6,R11,R12}
```

**Incorrect examples**

```
STMR5!,{R5,R4,R9}; value stored for R5 is unpredictable
LDMR2, {}; there must be at least one register in the list
```

### 3.4.7 PUSH and POP

Push registers onto, and pop registers off a full-descending stack.

**Syntax**

```
PUSH\{cond\} reglist
POP\{cond\} reglist
```

where:
- ‘\( \text{cond} \)’ is an optional condition code (see *Conditional execution on page 58*)
- ‘\( \text{reglist} \)’ is a non-empty list of registers, enclosed in braces. It can contain register ranges. It must be comma-separated if it contains more than one register or register range (see *Examples on page 69*).

PUSH and POP are synonyms for STMDB and LDM (or LDMIA) with the memory addresses for the access based on SP, and with the final address for the access written back to the SP. PUSH and POP are the preferred mnemonics in these cases.
Operation

PUSH stores registers on the stack in order of decreasing register numbers, with the highest numbered register using the highest memory address and the lowest numbered register using the lowest memory address.

POP loads registers from the stack in order of increasing register numbers, with the lowest numbered register using the lowest memory address and the highest numbered register using the highest memory address.

See *LDM and STM on page 68* for more information.

Restrictions

In these instructions:

- ‘reglist’ must not contain SP
- For the PUSH instruction, *reglist* must not contain PC
- For the POP instruction, *reglist* must not contain PC if it contains LR

When PC is in *reglist* in a POP instruction:

- bit[0] of the value loaded to the PC must be 1 for correct execution, and a branch occurs to this halfword-aligned address.
- If the instruction is conditional, it must be the last instruction in the IT block.

Condition flags

These instructions do not change the flags.

Examples

- `PUSH(R0,R4-R7)`
- `PUSH(R2,LR)`
- `POP(R0,R10,PC)`
3.4.8 LDREX and STREX

Load and store register exclusive.

Syntax

LDREX{cond} Rt, [Rn {, #offset}]
STREX{cond} Rd, Rt, [Rn {, #offset}]
LDREXB{cond} Rt, [Rn]
STREXB{cond} Rd, Rt, [Rn]
LDREXH{cond} Rt, [Rn]
STREXH{cond} Rd, Rt, [Rn]

where:
- ‘cond’ is an optional condition code (see Conditional execution on page 58)
- ‘Rd’ is the destination register for the returned status
- ‘Rt’ is the register to load or store
- ‘Rn’ is the register on which the memory address is based
- ‘offset’ is an optional offset applied to the value in Rn. If offset is omitted, the address is the value in Rn.

Operation

LDREX, LDREXB, and LDREXH load a word, byte, and halfword respectively from a memory address.

STREX, STREXB, and STREXH attempt to store a word, byte, and halfword respectively to a memory address. The address used in any store-exclusive instruction must be the same as the address in the most recently executed load-exclusive instruction. The value stored by the Store-exclusive instruction must also have the same data size as the value loaded by the preceding load-exclusive instruction. This means software must always use a load-exclusive instruction and a matching store-exclusive instruction to perform a synchronization operation, see Synchronization primitives on page 32.

If a store-exclusive instruction performs the store, it writes 0 to its destination register. If it does not perform the store, it writes 1 to its destination register. If the store-exclusive instruction writes 0 to the destination register, it is guaranteed that no other process in the system has accessed the memory location between the load-exclusive and store-exclusive instructions.

For reasons of performance, keep the number of instructions between corresponding load-exclusive and store-exclusive instruction to a minimum.

Note: The result of executing a store-exclusive instruction to an address that is different from that used in the preceding load-exclusive instruction is unpredictable.
Restrictions

In these instructions:

- Do not use PC
- Do not use SP for Rd and Rt
- For STREX, Rd must be different from both Rt and Rn
- The value of offset must be a multiple of four in the range 0-1020

Condition flags

These instructions do not change the flags.

Examples

MOVR1, #0x1; initialize the 'lock taken' value try
LDREXR0, [LockAddr]; load the lock value
CMPR0, #0; is the lock free?
ITTEQ; IT instruction for STREXEQ and CMPEQ
STREXEQRO, R1, [LockAddr]; try and claim the lock
CMPEQRO, #0; did this succeed?
BNREtry; no - try again
; yes - we have the lock

3.4.9 CLREX

Clear exclusive.

Syntax

CLREX{cond}

where:

`cond` is an optional condition code (see Conditional execution on page 58)

Operation

Use CLREX to make the next STREX, STREXB, or STREXH instruction write 1 to its destination register and fail to perform the store. It is useful in exception handler code to force the failure of the store exclusive if the exception occurs between a load exclusive instruction and the matching store exclusive instruction in a synchronization operation.

See Synchronization primitives on page 32 for more information.

Condition flags

These instructions do not change the flags.

Examples

CLREX
### 3.5 General data processing instructions

*Table 27* shows the data processing instructions.

<table>
<thead>
<tr>
<th>Mnemonic</th>
<th>Brief description</th>
<th>See</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>
3.5.1 **ADD, ADC, SUB, SBC, and RSB**

Add, add with carry, subtract, subtract with carry, and reverse subtract.

**Syntax**

\[ \text{op}\{S\}{\text{cond}}\{\text{Rd},\} \, \text{Rn, Operand2} \]
\[ \text{op}\{\text{cond}\} \{\text{Rd},\} \, \text{Rn, #imm12; ADD and SUB only} \]

where:
- ‘\text{op}’ is one of:
  - ADD: Add
  - ADC: Add with carry
  - SUB: Subtract
  - SBC: Subtract with carry
  - RSB: Reverse subtract
- ‘\text{S}’ is an optional suffix. If S is specified, the condition code flags are updated on the result of the operation (see *Conditional execution on page 58*).
- ‘\text{cond}’ is an optional condition code (see *Conditional execution on page 58*).
- ‘\text{Rd}’ is the destination register. If Rd is omitted, the destination register is Rn.
- ‘\text{Rn}’ is the register holding the first operand.
- ‘\text{Operand2}’ is a flexible second operand (see *Flexible second operand on page 53* for details of the options).
- ‘\text{imm12}’ is any value in the range 0—4095.

**Operation**

The ADD instruction adds the value of operand2 or imm12 to the value in Rn.

The ADC instruction adds the values in Rn and operand2, together with the carry flag.

The SUB instruction subtracts the value of operand2 or imm12 from the value in Rn.

The SBC instruction subtracts the value of operand2 from the value in Rn. If the carry flag is clear, the result is reduced by one.

The RSB instruction subtracts the value in Rn from the value of operand2. This is useful because of the wide range of options for operand2.

Use ADC and SBC to synthesize multiword arithmetic (see *Multiword arithmetic examples on page 75* and *ADR on page 61*).

ADDW is equivalent to the ADD syntax that uses the imm12 operand. SUBW is equivalent to the SUB syntax that uses the imm12 operand.
Restrictions

In these instructions:

- **Operand2** must be neither SP nor PC
- **Rd** can be SP only in ADD and SUB, and only with the following additional restrictions:
  - **Rn** must also be SP
  - Any shift in operand2 must be limited to a maximum of three bits using LSL
- **Rn** can be SP only in ADD and SUB
- **Rd** can be PC only in the ADD(cond) PC, PC, Rm instruction where:
  - You must not specify the S suffix
  - **Rm** must be neither PC nor SP
  - If the instruction is conditional, it must be the last instruction in the IT block
- With the exception of the ADD(cond) PC, PC, Rm instruction, **Rn** can be PC only in ADD and SUB, and only with the following additional restrictions:
  - You must not specify the S suffix
  - The second operand must be a constant in the range 0 to 4095

Note: 1. When using the PC for an addition or a subtraction, bits[1:0] of the PC are rounded to b00 before performing the calculation, making the base address for the calculation word-aligned.
2. If you want to generate the address of an instruction, you have to adjust the constant based on the value of the PC. ARM recommends that you use the ADR instruction instead of ADD or SUB with Rn equal to the PC, because your assembler automatically calculates the correct constant for the ADR instruction.

When **Rd** is PC in the ADD(cond) PC, PC, Rm instruction:

- bit[0] of the value written to the PC is ignored
- A branch occurs to the address created by forcing bit[0] of that value to 0

Condition flags

If S is specified, these instructions update the N, Z, C and V flags according to the result.

Examples

```
ADDR2, R1, R3
SUBSR8, R6, #240; sets the flags on the result
RSBR4, R4, #1280; subtracts contents of R4 from 1280
ADCHIR11, R0, R3; only executed if C flag set and Z flag clear
```

Multiword arithmetic examples

**Specific example 4: 64-bit addition** shows two instructions that add a 64-bit integer contained in R2 and R3 to another 64-bit integer contained in R0 and R1, and place the result in R4 and R5.

**Specific example 4: 64-bit addition**

```
ADDSR4, R0, R2; add the least significant words
ADCR5, R1, R3; add the most significant words with carry
```
Multiword values do not have to use consecutive registers. Specific example 5: 96-bit subtraction shows instructions that subtract a 96-bit integer contained in R9, R1, and R11 from another contained in R6, R2, and R8. The example stores the result in R6, R9, and R2.

Specific example 5: 96-bit subtraction

SUBSR6, R6, R9; subtract the least significant words
SBCSR9, R2, R1; subtract the middle words with carry
SBCR2, R8, R11; subtract the most significant words with carry

3.5.2 AND, ORR, EOR, BIC, and ORN

Logical AND, OR, exclusive OR, bit clear, and OR NOT.

Syntax

\[ \text{op}(S)(\text{cond}) \{\text{Rd},\} \text{ Rn, Operand2} \]

where:
- ‘op’ is one of:
  - AND: Logical AND
  - ORR: Logical OR or bit set
  - EOR: Logical exclusive OR
  - BIC: Logical AND NOT or bit clear
  - ORN: Logical OR NOT
- ‘S’ is an optional suffix. If S is specified, the condition code flags are updated on the result of the operation (see Conditional execution on page 58).
- ‘cond’ is an optional condition code (see Conditional execution on page 58)
- ‘Rd’ is the destination register
- ‘Rn’ is the register holding the first operand
- ‘Operand2’ is a flexible second operand (see Flexible second operand on page 53 for details of the options).

Operation

The AND, EOR, and ORR instructions perform bitwise AND, exclusive OR, and OR operations on the values in Rn and operand2.

The BIC instruction performs an AND operation on the bits in Rn with the complements of the corresponding bits in the value of operand2.

The ORN instruction performs an OR operation on the bits in Rn with the complements of the corresponding bits in the value of operand2.

Restrictions

Do not use either SP or PC.
Condition flags

If S is specified, these instructions:
- Update the N and Z flags according to the result
- Can update the C flag during the calculation of operand2 (see Flexible second operand on page 53)
- Do not affect the V flag

Examples

- ANDR9, R2, #0xFF00
- ORREQR2, R0, R5
- ANDSR9, R8, #0x19
- EORSR7, R11, #0x18181818
- BICR0, R1, #0xab
- ORNR7, R11, R14, ROR #4
- ORNSR7, R11, R14, ASR #32

3.5.3 ASR, LSL, LSR, ROR, and RRX

Arithmetic shift right, logical shift left, logical shift right, rotate right, and rotate right with extend.

Syntax

- op(S){cond} Rd, Rm, Rs
- op(S){cond} Rd, Rm, #n
- RRX(S){cond} Rd, Rm

where:
- ‘op’ is one of:
  - ASR: Arithmetic shift right
  - LSL: Logical shift left
  - LSR: Logical shift right
  - ROR: Rotate right
- ‘S’ is an optional suffix. If S is specified, the condition code flags are updated on the result of the operation (see Conditional execution on page 58)
- ‘Rd’ is the destination register
- ‘Rm’ is the register holding the value to be shifted
- ‘Rs’ is the register holding the shift length to apply to the value Rm. Only the least significant byte is used and can be in the range 0 to 255.
- ‘n’ is the shift length. The range of shift lengths depend on the instruction as follows:
  - ASR: Shift length from 1 to 32
  - LSL: Shift length from 0 to 31
  - LSR: Shift length from 1 to 32
  - ROR: Shift length from 1 to 31

Note: MOV(S){cond} Rd, Rm is the preferred syntax for LSL(S){cond} Rd, Rm, #0.
Operation

ASR, LSL, LSR, and ROR move the bits in the register \( Rm \) to the left or right by the number of places specified by constant \( n \) or register \( Rs \).

RRX moves the bits in register \( Rm \) to the right by 1.

In all these instructions, the result is written to \( Rd \), but the value in register \( Rm \) remains unchanged. For details on what result is generated by the different instructions (see *Shift operations on page 54*).

Restrictions

Do not use either SP or PC.

Condition flags

If S is specified:

- These instructions update the N and Z flags according to the result
- The C flag is updated to the last bit shifted out, except when the shift length is 0 (see *Shift operations on page 54*).

Examples

\[
\text{ASRR7, R8, } #9; \text{ arithmetic shift right by 9 bits}
\]
\[
\text{LSLSR1, R2, } #3; \text{ logical shift left by 3 bits with flag update}
\]
\[
\text{LSRR4, R5, } #6; \text{ logical shift right by 6 bits}
\]
\[
\text{RORR4, R5, R6; rotate right by the value in the bottom byte of R6}
\]
\[
\text{RRXR4, R5; rotate right with extend}
\]

3.5.4 CLZ

Count leading zeros.

Syntax

\[\text{CLZ} \{\text{cond}\} \ Rd, \ Rm\]

where:

- ‘\text{cond}’ is an optional condition code (see *Conditional execution on page 56*)
- ‘\(Rd\)’ is the destination register
- ‘\(Rm\)’ is the operand register

Operation

The CLZ instruction counts the number of leading zeros in the value in \( Rm \) and returns the result in \( Rd \). The result value is 32 if no bits are set in the source register, and zero if bit[31] is set.

Restrictions

Do not use either SP or PC.

Condition flags

This instruction does not change the flags.
Examples

CLZR4, R9
CLZNER2, R3

3.5.5 CMP and CMN

Compare and compare negative.

Syntax

CMP{cond} Rn, Operand2
CMN{cond} Rn, Operand2

where:

● ‘cond’ is an optional condition code (see Conditional execution on page 58)
● ‘Rn’ is the register holding the first operand
● ‘Operand2’ is a flexible second operand (see Flexible second operand on page 53) for details of the options.

Operation

These instructions compare the value in a register with operand2. They update the condition flags on the result, but do not write the result to a register.

The CMP instruction subtracts the value of operand2 from the value in Rn. This is the same as a SUBS instruction, except that the result is discarded.

The CMN instruction adds the value of operand2 to the value in Rn. This is the same as an ADDS instruction, except that the result is discarded.

Restrictions

In these instructions:

• Do not use PC
• Operand2 must not be SP

Condition flags

These instructions update the N, Z, C and V flags according to the result.

Examples

CMPR2, R9
CMNR0, #6400
CMPGTSP, R7, LSL #2
3.5.6 MOV and MVN

Move and move NOT.

Syntax

\[
\begin{align*}
\text{MOV}\{s\}\{cond\} & \text{ Rd, Operand2} \\
\text{MOV}\{cond\} & \text{ Rd, } \#\text{imm16} \\
\text{MVN}\{s\}\{cond\} & \text{ Rd, Operand2}
\end{align*}
\]

where:
- ‘s’ is an optional suffix. If s is specified, the condition code flags are updated on the result of the operation (see Conditional execution on page 58).
- ‘cond’ is an optional condition code (see Conditional execution on page 58).
- ‘Rd’ is the destination register.
- ‘Operand2’ is a flexible second operand (see Flexible second operand on page 53) for details of the options.
- ‘imm16’ is any value in the range 0—65535.

Operation

The MOV instruction copies the value of operand2 into Rd.

When operand2 in a MOV instruction is a register with a shift other than LSL #0, the preferred syntax is the corresponding shift instruction:
- \text{ASR}\{s\}\{cond\} Rd, Rm, \#n is the preferred syntax for \text{MOV}\{s\}\{cond\} Rd, Rm, ASR \#n.
- \text{LSL}\{s\}\{cond\} Rd, Rm, \#n is the preferred syntax for \text{MOV}\{s\}\{cond\} Rd, Rm, LSL \#n if n \neq 0.
- \text{LSR}\{s\}\{cond\} Rd, Rm, \#n is the preferred syntax for \text{MOV}\{s\}\{cond\} Rd, Rm, LSR \#n.
- \text{ROR}\{s\}\{cond\} Rd, Rm, \#n is the preferred syntax for \text{MOV}\{s\}\{cond\} Rd, Rm, ROR \#n.
- \text{RRX}\{s\}\{cond\} Rd, Rm is the preferred syntax for \text{MOV}\{s\}\{cond\} Rd, Rm, RRX.

Also, the MOV instruction permits additional forms of operand2 as synonyms for shift instructions:
- \text{MOV}\{s\}\{cond\} Rd, Rm, ASR Rs is a synonym for \text{ASR}\{s\}\{cond\} Rd, Rm, Rs.
- \text{MOV}\{s\}\{cond\} Rd, Rm, LSL Rs is a synonym for \text{LSL}\{s\}\{cond\} Rd, Rm, Rs.
- \text{MOV}\{s\}\{cond\} Rd, Rm, LSR Rs is a synonym for \text{LSR}\{s\}\{cond\} Rd, Rm, Rs.
- \text{MOV}\{s\}\{cond\} Rd, Rm, ROR Rs is a synonym for \text{ROR}\{s\}\{cond\} Rd, Rm, Rs.

See \text{ASR, LSL, LSR, ROR, and RRX on page 77}.

The MVN instruction takes the value of operand2, performs a bitwise logical NOT operation on the value, and places the result into Rd.

Note: The MOVW instruction provides the same function as MOV, but is restricted to using the imm16 operand.
Restrictions

You can use SP and PC only in the MOV instruction, with the following restrictions:

- The second operand must be a register without shift
- You must not specify the S suffix

When Rd is PC in a MOV instruction:

- bit[0] of the value written to the PC is ignored
- A branch occurs to the address created by forcing bit[0] of that value to 0.

Note: Though it is possible to use MOV as a branch instruction, ARM strongly recommends the use of a BX or BLX instruction to branch for software portability to the ARM instruction set.

Condition flags

If S is specified, these instructions:

- Update the N and Z flags according to the result
- Can update the C flag during the calculation of operand2 (see Flexible second operand on page 53).
- Do not affect the V flag

Example

MOVSR11, #0x000B; write value of 0x000B to R11, flags get updated
MOVRL, #0xFA05; write value of 0xFA05 to R1, flags are not updated
MOVSR10, R12; write value in R12 to R10, flags get updated
MOVRR3, #23; write value of 23 to R3
MOVSP, SP; write value of stack pointer to R8
MOVSR2, #0xF; write value of 0xFFFFFFFF0 (bitwise inverse of 0xF) ; to the R2 and update flags

3.5.7 MOVT

Move top.

Syntax

MOVT{cond} Rd, #imm16

where:

- ‘cond’ is an optional condition code (see Conditional execution on page 58)
- ‘Rd’ is the destination register
- ‘imm16’ is a 16-bit immediate constant

Operation

MOVT writes a 16-bit immediate value, imm16, to the top halfword, Rd[31:16], of its destination register. The write does not affect Rd[15:0].

The MOV, MOVT instruction pair enables you to generate any 32-bit constant.

Restrictions

Rd must be neither SP nor PC.
Condition flags

This instruction does not change the flags.

Examples

MOVTR3, #0xF123; write 0xF123 to upper halfword of R3, lower halfword ; and APSR are unchanged

3.5.8 REV, REV16, REVSH, and RBIT

Reverse bytes and reverse bits.

Syntax

op{cond} Rd, Rn

where:

- ‘op’ is one of:
  - REV: Reverse byte order in a word
  - REV16: Reverse byte order in each halfword independently
  - REVSH: Reverse byte order in the bottom halfword, and sign extends to 32 bits
  - RBIT: Reverse the bit order in a 32-bit word
- ‘cond’ is an optional condition code (see Conditional execution on page 58)
- ‘Rd’ is the destination register
- ‘Rn’ is the register holding the operand

Operation

Use these instructions to change endianness of data:

- REV: Converts 32-bit big-endian data into little-endian data or 32-bit little-endian data into big-endian data.
- REV16: Converts 16-bit big-endian data into little-endian data or 16-bit little-endian data into big-endian data.
- REVSH: Converts either:
  - 16-bit signed big-endian data into 32-bit signed little-endian data
  - 16-bit signed little-endian data into 32-bit signed big-endian data

Restrictions

Do not use either SP or PC.

Condition flags

These instructions do not change the flags.

Examples

REVR3, R7; reverse byte order of value in R7 and write it to R3
REV16 R0, R0; reverse byte order of each 16-bit halfword in R0
REVSH R0, R5 ; reverse Signed Halfword
REVHS R3, R7 ; reverse with Higher or Same condition
RBIT R7, R8 ; reverse bit order of value in R8 and write the result to R7
3.5.9 TST and TEQ

Test bits and test equivalence.

Syntax

TST{cond} Rn, Operand2
TEQ{cond} Rn, Operand2

where:
- ‘cond’ is an optional condition code (see Conditional execution on page 58)
- ‘Rn’ is the register holding the first operand
- ‘Operand2’ is a flexible second operand (see Flexible second operand on page 53) for details of the options.

Operation

These instructions test the value in a register against operand2. They update the condition flags based on the result, but do not write the result to a register.

The TST instruction performs a bitwise AND operation on the value in Rn and the value of operand2. This is the same as the ANDS instruction, except that it discards the result.

To test whether a bit of Rn is 0 or 1, use the TST instruction with an operand2 constant that has that bit set to 1 and all other bits cleared to 0.

The TEQ instruction performs a bitwise exclusive OR operation on the value in Rn and the value of operand2. This is the same as the EORS instruction, except that it discards the result.

Use the TEQ instruction to test if two values are equal without affecting the V or C flags. TEQ is also useful for testing the sign of a value. After the comparison, the N flag is the logical exclusive OR of the sign bits of the two operands.

Restrictions

Do not use either SP or PC.

Condition flags

These instructions:
- Update the N and Z flags according to the result
- Can update the C flag during the calculation of operand2 (see Flexible second operand on page 53).
- Do not affect the V flag

Examples

TSTR0, #0x3F8; perform bitwise AND of R0 value to 0x3F8, ; APSR is updated but result is discarded
TEQEQR10, R9; conditionally test if value in R10 is equal to ; value in R9, APSR is updated but result is discarded
3.6 Multiply and divide instructions

</tbody>
</table>

3.6.1 MUL, MLA, and MLS

Multiply, multiply with accumulate, and multiply with subtract, using 32-bit operands, and producing a 32-bit result.

Syntax

MUL($\{\text{cond}\}$ (Rd,) Rn, Rm ; Multiply
MLA(\text{cond}) Rd, Rn, Rm, Ra ; Multiply with accumulate
MLS(\text{cond}) Rd, Rn, Rm, Ra ; Multiply with subtract

where:
- ‘\text{cond}’ is an optional condition code (see Conditional execution on page 58)
- ‘\text{S}’ is an optional suffix. If S is specified, the condition code flags are updated on the result of the operation (see Conditional execution on page 58).
- ‘\text{Rd}’ is the destination register. If \text{Rd} is omitted, the destination register is \text{Rn}
- ‘\text{Rn}’, ‘\text{Rm}’ are registers holding the values to be multiplied
- ‘\text{Ra}’ is a register holding the value to be added to or subtracted from
Operation
The MUL instruction multiplies the values from \( R_n \) and \( R_m \), and places the least significant 32 bits of the result in \( R_d \).

The MLA instruction multiplies the values from \( R_n \) and \( R_m \), adds the value from \( R_a \), and places the least significant 32 bits of the result in \( R_d \).

The MLS instruction multiplies the values from \( R_n \) and \( R_m \), subtracts the product from the value from \( R_a \), and places the least significant 32 bits of the result in \( R_d \).

The results of these instructions do not depend on whether the operands are signed or unsigned.

Restrictions
In these instructions, do not use \( SP \) and do not use \( PC \).

If you use the \( S \) suffix with the MUL instruction:
- \( R_d \), \( R_n \), and \( R_m \) must all be in the range \( R_0 \) to \( R_7 \)
- \( R_d \) must be the same as \( R_m \)
- You must not use the \( cond \) suffix

Condition flags
If \( S \) is specified, the MUL instruction:
- Updates the \( N \) and \( Z \) flags according to the result
- Does not affect the \( C \) and \( V \) flags

Examples
MULR10, R2, R5; multiply, \( R_{10} = R_2 \times R_5 \)
MLAR10, R2, R1, R5; multiply with accumulate, \( R_{10} = (R_2 \times R_1) + R_5 \)
MULSR0, R2, R2; multiply with flag update, \( R_0 = R_2 \times R_2 \)
MULLTR2, R3, R2; conditionally multiply, \( R_2 = R_3 \times R_2 \)
MLSR4, R5, R6, R7; multiply with subtract, \( R_4 = R_7 - (R_5 \times R_6) \)
3.6.2 UMULL, UMLAL, SMULL, and SMLAL

Signed and unsigned long multiply, with optional accumulate, using 32-bit operands and producing a 64-bit result.

Syntax

\[ op\{cond\} \text{RdLo, RdHi, Rn, Rm} \]

where:
- ‘op’ is one of:
  - UMULL: Unsigned long multiply
  - UMLAL: Unsigned long multiply, with accumulate
  - SMULL: Signed long multiply
  - SMLAL: Signed long multiply, with accumulate
- ‘cond’ is an optional condition code (see Conditional execution on page 58)
- ‘RdHi, RdLo’ are the destination registers. For UMLAL and SMLAL, they also hold the accumulating value.
- ‘Rn, Rm’ are registers holding the operands

Operation

The UMULL instruction interprets the values from \(Rn\) and \(Rm\) as unsigned integers. It multiplies these integers and places the least significant 32 bits of the result in \(RdLo\), and the most significant 32 bits of the result in \(RdHi\).

The UMLAL instruction interprets the values from \(Rn\) and \(Rm\) as unsigned integers. It multiplies these integers, adds the 64-bit result to the 64-bit unsigned integer contained in \(RdHi\) and \(RdLo\), and writes the result back to \(RdHi\) and \(RdLo\).

The SMULL instruction interprets the values from \(Rn\) and \(Rm\) as two’s complement signed integers. It multiplies these integers and places the least significant 32 bits of the result in \(RdLo\), and the most significant 32 bits of the result in \(RdHi\).

The SMLAL instruction interprets the values from \(Rn\) and \(Rm\) as two’s complement signed integers. It multiplies these integers, adds the 64-bit result to the 64-bit signed integer contained in \(RdHi\) and \(RdLo\), and writes the result back to \(RdHi\) and \(RdLo\).

Restrictions

In these instructions:
- Do not use either SP or PC
- \(RdHi\) and \(RdLo\) must be different registers

Condition flags

These instructions do not affect the condition code flags.

Examples

\[
\begin{align*}
\text{UMULLR0, R4, R5, R6; unsigned } & (R4,R0) = R5 \times R6 \\
\text{SMLALR4, R5, R3, R8; signed } & (R5,R4) = (R5,R4) + R3 \times R8
\end{align*}
\]
3.6.3 SDIV and UDIV

Signed divide and unsigned divide.

Syntax

SDIV{cond} {Rd,} Rn, Rm
UDIV{cond} {Rd,} Rn, Rm

where:

- ‘cond’ is an optional condition code (see Conditional execution on page 58)
- ‘Rd’ is the destination register. If Rd is omitted, the destination register is Rn
- ‘Rn’ is the register holding the value to be divided
- ‘Rm’ is a register holding the divisor

Operation

SDIV performs a signed integer division of the value in Rn by the value in Rm.
UDIV performs an unsigned integer division of the value in Rn by the value in Rm.

For both instructions, if the value in Rn is not divisible by the value in Rm, the result is rounded towards zero.

Restrictions

Do not use either SP or PC.

Condition flags

These instructions do not change the flags.

Examples

SDIVR0, R2, R4; signed divide, R0 = R2/R4
UDIVR8, R8, R1; unsigned divide, R8 = R8/R1
3.7 Saturating instructions

This section describes the saturating instructions, SSAT and USAT.

3.7.1 SSAT and USAT

Signed saturate and unsigned saturate to any bit position, with optional shift before saturating.

Syntax

```
op{cond} Rd, #n, Rm {, shift #s}
```

where:

- ‘op’ is one of the following:
  - SSAT: Saturates a signed value to a signed range
  - USAT: Saturates a signed value to an unsigned range
- ‘cond’ is an optional condition code (see Conditional execution on page 58)
- ‘Rd’ is the destination register.
- ‘n’ specifies the bit position to saturate to:
  - n ranges from 1 to 32 for SSAT
  - n ranges from 0 to 31 for USAT
- ‘Rm’ is the register containing the value to saturate
- ‘shift #s’ is an optional shift applied to Rm before saturating. It must be one of the following:
  - ASR #s where s is in the range 1 to 31
  - LSL #s where s is in the range 0 to 31

Operation

These instructions saturate to a signed or unsigned n-bit value.

The SSAT instruction applies the specified shift, then saturates to the signed range:

```
-2^{n-1} \leq x \leq 2^{n-1}-1.
```

The USAT instruction applies the specified shift, then saturates to the unsigned range:

```
0 \leq x \leq 2^n-1.
```

For signed n-bit saturation using SSAT, this means that:

- If the value to be saturated is less than -2^{n-1}, the result returned is -2^{n-1}
- If the value to be saturated is greater than 2^{n-1}-1, the result returned is 2^{n-1}-1
- Otherwise, the result returned is the same as the value to be saturated.

For unsigned n-bit saturation using USAT, this means that:

- If the value to be saturated is less than 0, the result returned is 0
- If the value to be saturated is greater than 2^n-1, the result returned is 2^n-1
- Otherwise, the result returned is the same as the value to be saturated.

If the returned result is different from the value to be saturated, it is called saturation. If saturation occurs, the instruction sets the Q flag to 1 in the APSR. Otherwise, it leaves the Q flag unchanged. To clear the Q flag to 0, you must use the MSR instruction, see MSR on page 102.
To read the state of the Q flag, use the MRS instruction (see MRS on page 101).

Restrictions
Do not use either SP or PC.

Condition flags
These instructions do not affect the condition code flags.
If saturation occurs, these instructions set the Q flag to 1.

Examples
SSATR7, #16, R7, LSL #4; logical shift left value in R7 by 4, then
; saturate it as a signed 16-bit value and
; write it back to R7
USATNER0, #7, R5; conditionally saturate value in R5 as an
; unsigned 7 bit value and write it to R0

3.8 Bitfield instructions

Table 29 shows the instructions that operate on adjacent sets of bits in registers or bitfields.

Table 29. Packing and unpacking instructions

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
3.8.1 BFC and BFI
Bit Field Clear and Bit Field Insert.

Syntax

BFC{cond} Rd, #lsb, #width
BFI{cond} Rd, Rn, #lsb, #width

where:
- ‘cond’ is an optional condition code, see Conditional execution on page 58.
- ‘Rd’ is the destination register.
- ‘Rn’ is the source register.
- ‘lsb’ is the position of the least significant bit of the bitfield. lsb must be in the range 0 to 31.
- ‘width’ is the width of the bitfield and must be in the range 1 to 32-lsb.

Operation
BFC clears a bitfield in a register. It clears width bits in Rd, starting at the low bit position lsb. Other bits in Rd are unchanged.

BFI copies a bitfield into one register from another register. It replaces width bits in Rd starting at the low bit position lsb, with width bits from Rn starting at bit[0]. Other bits in Rd are unchanged.

Restrictions
Do not use SP and do not use PC.

Condition flags
These instructions do not affect the flags.

Examples

BFC R4, #8, #12 ; Clear bit 8 to bit 19 (12 bits) of R4 to 0
BFI R9, R2, #8, #12 ; Replace bit 8 to bit 19 (12 bits) of R9 with ; bit 0 to bit 11 from R2

3.8.2 SBFX and UBFX
Signed Bit Field Extract and Unsigned Bit Field Extract.

Syntax

SBFX{cond} Rd, Rn, #lsb, #width
UBFX{cond} Rd, Rn, #lsb, #width
where:
- ‘cond’ is an optional condition code, see Conditional execution on page 58.
- ‘Rd’ is the destination register.
- ‘Rn’ is the source register.
- ‘lsb’ is the position of the least significant bit of the bitfield. lsb must be in the range 0 to 31.
- ‘width’ is the width of the bitfield and must be in the range 1 to 32-lsb.

**Operation**

SBFX extracts a bitfield from one register, sign extends it to 32 bits, and writes the result to the destination register.

UBFX extracts a bitfield from one register, zero extends it to 32 bits, and writes the result to the destination register.

**Restrictions**

Do not use SP and do not use PC.

**Condition flags**

These instructions do not affect the flags.

**Examples**

```
SBFX  R0, R1, #20, #4 ; Extract bit 20 to bit 23 (4 bits) from R1 and sign 
                      ; extend to 32 bits and then write the result to R0.
UBFX  R8, R11, #9, #10 ; Extract bit 9 to bit 18 (10 bits) from R11 and zero 
                      ; extend to 32 bits and then write the result to R8
```

### 3.8.3 SXT and UXT

Sign extend and Zero extend.

**Syntax**

```
SXTextend(cond) (Rd,), Rm {, ROR #n}
UXTextend(cond) (Rd), Rm {, ROR #n}
```

where:
- ‘extend’ is one of:
  - B: Extends an 8-bit value to a 32-bit value.
  - H: Extends a 16-bit value to a 32-bit value.
- ‘cond’ is an optional condition code, see Conditional execution on page 58.
- ‘Rd’ is the destination register.
- ‘Rm’ is the register holding the value to extend.
- ROR #n is one of:
  - ROR #8: Value from Rm is rotated right 8 bits.
  - ROR #16: Value from Rm is rotated right 16 bits.
  - ROR #24: Value from Rm is rotated right 24 bits.
  - If ROR #n is omitted, no rotation is performed.
Operation

These instructions do the following:

1. Rotate the value from \( R_m \) right by 0, 8, 16 or 24 bits.
2. Extract bits from the resulting value:
   - SXTB extracts bits[7:0] and sign extends to 32 bits.
   - UXTB extracts bits[7:0] and zero extends to 32 bits.
   - SXTH extracts bits[15:0] and sign extends to 32 bits.
   - UXTH extracts bits[15:0] and zero extends to 32 bits.

Restrictions

Do not use SP and do not use PC.

Condition flags

These instructions do not affect the flags.

Examples

- \( \text{SXTH} \ R_4, R_6, \text{ROR} \ #16 \) ; Rotate R6 right by 16 bits, then obtain the lower halfword of the result and then sign extend to 32 bits and write the result to R4.
- \( \text{UXTB} \ R_3, R_{10} \) ; Extract lowest byte of the value in R10 and zero extend it, and write the result to R3

3.8.4 Branch and control instructions

Table 30 shows the branch and control instructions:

<table>

<tr>
<td>TBH</td>
<td>Table Branch Halfword</td>
<td>( \text{TBB and TBH on page 97} )</td>
</tr>
</tbody>
</table>
### 3.8.5 B, BL, BX, and BLX

Branch instructions.

**Syntax**

\[
\begin{align*}
B\{\text{cond}\} & \quad \text{label} \\
BL\{\text{cond}\} & \quad \text{label} \\
BX\{\text{cond}\} & \quad Rm \\
BLX\{\text{cond}\} & \quad Rm
\end{align*}
\]

where:
- ‘B’ is branch (immediate).
- ‘BL’ is branch with link (immediate).
- ‘BX’ is branch indirect (register).
- ‘BLX’ is branch indirect with link (register).
- ‘cond’ is an optional condition code, see Conditional execution on page 58.
- ‘label’ is a PC-relative expression. See PC-relative expressions on page 57.
- ‘Rm’ is a register that indicates an address to branch to. Bit[0] of the value in Rm must be 1, but the address to branch to is created by changing bit[0] to 0.

**Operation**

All these instructions cause a branch to label, or to the address indicated in Rm. In addition:
- The BL and BLX instructions write the address of the next instruction to LR (the link register, R14).
- The BX and BLX instructions cause a UsageFault exception if bit[0] of Rm is 0.

B \text{cond} \text{label} is the only conditional instruction that can be either inside or outside an IT block. All other branch instructions must be conditional inside an IT block, and must be unconditional outside the IT block, see IT on page 95.

*Table 31* shows the ranges for the various branch instructions.

#### Table 31. Branch ranges

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Branch range</th>
</tr>
</thead>
<tbody>
<tr>
<td>B label</td>
<td>-16 MB to +16 MB</td>
</tr>
<tr>
<td>B\text{cond} \text{label} (outside IT block)</td>
<td>-1 MB to +1 MB</td>
</tr>
<tr>
<td>B\text{cond} \text{label} (inside IT block)</td>
<td>-16 MB to +16 MB</td>
</tr>
<tr>
<td>BL{\text{cond}} \text{label}</td>
<td>-16 MB to +16 MB</td>
</tr>
<tr>
<td>BX{\text{cond}} \text{Rm}</td>
<td>Any value in register</td>
</tr>
<tr>
<td>BLX{\text{cond}} \text{Rm}</td>
<td>Any value in register</td>
</tr>
</tbody>
</table>

You might have to use the .W suffix to get the maximum branch range. See Instruction width selection on page 60.
Restrictions

The restrictions are:

- Do not use PC in the BLX instruction
- For BX and BLX, bit[0] of Rm must be 1 for correct execution but a branch occurs to the target address created by changing bit[0] to 0
- When any of these instructions is inside an IT block, it must be the last instruction of the IT block.

Bcond is the only conditional instruction that is not required to be inside an IT block. However, it has a longer branch range when it is inside an IT block.

Condition flags

These instructions do not change the flags.

Examples

\begin{verbatim}
B loopA ; Branch to loopA
BLE ng ; Conditionally branch to label ng
B.W target ; Branch to target within 16MB range
BEQ target ; Conditionally branch to target
BEQ.W target ; Conditionally branch to target within 1MB
BL func ; Branch with link (Call) to function func, return address ; stored in LR
BX LR ; Return from function call
BXNE R0 ; Conditionally branch to address stored in R0
BLX R0 ; Branch with link and exchange (Call) to a address stored ; in R0
\end{verbatim}

3.8.6 CBZ and CBNZ

Compare and branch on zero, compare and branch on non-zero.

Syntax

CBZ Rn, label
CBNZ Rn, label

where:

- ‘Rn’ is the register holding the operand.
- ‘label’ is the branch destination.

Operation

Use the CBZ or CBNZ instructions to avoid changing the condition code flags and to reduce the number of instructions.

CBZ Rn, label does not change condition flags but is otherwise equivalent to:

\begin{verbatim}
CMP Rn, #0
BEQ label
\end{verbatim}

CBNZ Rn, label does not change condition flags but is otherwise equivalent to:

\begin{verbatim}
CMP Rn, #0
BNE label
\end{verbatim}
Restrictions
The restrictions are:
- $Rn$ must be in the range of R0 to R7
- The branch destination must be within 4 to 130 bytes after the instruction
- These instructions must not be used inside an IT block.

Condition flags
These instructions do not change the flags.

Examples

<table>
<thead>
<tr>
<th>Instruction</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CBZ R5, target</td>
<td>Forward branch if R5 is zero</td>
</tr>
<tr>
<td>CBNZ R0, target</td>
<td>Forward branch if R0 is not zero</td>
</tr>
</tbody>
</table>

3.8.7 IT
If-Then condition instruction.

Syntax

$$\text{IT}\{x(y(z))\} \text{ cond}$$

where:
- ‘$x$’ specifies the condition switch for the second instruction in the IT block.
- ‘$y$’ specifies the condition switch for the third instruction in the IT block.
- ‘$z$’ specifies the condition switch for the fourth instruction in the IT block.
- ‘$\text{cond}$’ specifies the condition for the first instruction in the IT block.

The condition switch for the second, third and fourth instruction in the IT block can be either:
- T: Then. Applies the condition $\text{cond}$ to the instruction.
- E: Else. Applies the inverse condition of $\text{cond}$ to the instruction.

- a) It is possible to use AL (the always condition) for cond in an IT instruction. If this is done, all of the instructions in the IT block must be unconditional, and each of $x$, $y$, and $z$ must be T or omitted but not E.

Operation
The IT instruction makes up to four following instructions conditional. The conditions can be all the same, or some of them can be the logical inverse of the others. The conditional instructions following the IT instruction form the IT block.

The instructions in the IT block, including any branches, must specify the condition in the $\{\text{cond}\}$ part of their syntax.

Your assembler might be able to generate the required IT instructions for conditional instructions automatically, so that you do not need to write them yourself. See your assembler documentation for details.

A BKPT instruction in an IT block is always executed, even if its condition fails.
Exceptions can be taken between an IT instruction and the corresponding IT block, or within an IT block. Such an exception results in entry to the appropriate exception handler, with suitable return information in LR and stacked PSR.

Instructions designed for use for exception returns can be used as normal to return from the exception, and execution of the IT block resumes correctly. This is the only way that a PC-modifying instruction is permitted to branch to an instruction in an IT block.

Restrictions

The following instructions are not permitted in an IT block:

- IT
- CBZ and CBNZ
- CPSID and CPSIE.

Other restrictions when using an IT block are:

- A branch or any instruction that modifies the PC must either be outside an IT block or must be the last instruction inside the IT block. These are:
  - ADD PC, PC, Rm
  - MOV PC, Rm
  - B, BL, BX, BLX
  - Any LDM, LDR, or POP instruction that writes to the PC
  - TBB and TBH
- Do not branch to any instruction inside an IT block, except when returning from an exception handler
- All conditional instructions except \texttt{B}\texttt\{cond\} must be inside an IT block. \texttt{B}\texttt\{cond\} can be either outside or inside an IT block but has a larger branch range if it is inside one
- Each instruction inside the IT block must specify a condition code suffix that is either the same or logical inverse as for the other instructions in the block.

Your assembler might place extra restrictions on the use of IT blocks, such as prohibiting the use of assembler directives within them.

Condition flags

This instruction does not change the flags.

Example

\begin{verbatim}
ITTE NE          ; Next 3 instructions are conditional
ANDNE R0, R0, R1 ; ANDNE does not update condition flags
ADDSNE R2, R2, #1 ; ADDSNE updates condition flags
MOVEQ R2, R3    ; Conditional move

CMP R0, #9      ; Convert R0 hex value (0 to 15) into ASCII
                ; {'0'-'9', 'A'-'F'}
ITTE GT          ; Next 2 instructions are conditional
ADDGT R1, R0, #55 ; Convert 0xA -> 'A'
ADDLE R1, R0, #48 ; Convert 0x0 -> '0'

IT GT            ; IT block with only one conditional instruction
\end{verbatim}
ADDGT R1, R1, #1 ; Increment R1 conditionally

ITTEE EQ ; Next 4 instructions are conditional
MOVEQ R0, R1 ; Conditional move
ADDEQ R2, R2, #10 ; Conditional add
ANDNE R3, R3, #1 ; Conditional AND
BNE.W dloop ; Branch instruction can only be used in the last instruction of an IT block

IT NE ; Next instruction is conditional
ADD R0, R0, R1 ; Syntax error: no condition code used in IT block

3.8.8 TBB and TBH

Table Branch Byte and Table Branch Halfword.

Syntax

TBB [Rn, Rm]
TBH [Rn, Rm, LSL #1]

where:

● ‘Rn’ is the register containing the address of the table of branch lengths.
  If Rn is PC, then the address of the table is the address of the byte immediately following the TBB or TBH instruction.

● ‘Rm’ is the index register. This contains an index into the table. For halfword tables, LSL #1 doubles the value in Rm to form the right offset into the table.

Operation

These instructions cause a PC-relative forward branch using a table of single byte offsets for TBB, or halfword offsets for TBH. Rn provides a pointer to the table, and Rm supplies an index into the table. For TBB the branch offset is twice the unsigned value of the byte returned from the table. And for TBH the branch offset is twice the unsigned value of the halfword returned from the table. The branch occurs to the address at that offset from the address of the byte immediately after the TBB or TBH instruction.

Restrictions

The restrictions are:

● Rn must not be SP
● Rm must not be SP and must not be PC
● When any of these instructions is used inside an IT block, it must be the last instruction of the IT block.

Condition flags

These instructions do not change the flags.
Examples

ADR.W R0, BranchTable_BYTE
TBB [R0, R1] ; R1 is the index, R0 is the base address of the branch table

Case1
; an instruction sequence follows
Case2
; an instruction sequence follows
Case3
; an instruction sequence follows
BranchTable_BYTE
DCB 0 ; Case1 offset calculation
DCB ((Case2-Case1)/2) ; Case2 offset calculation
DCB ((Case3-Case1)/2) ; Case3 offset calculation

TBH [PC, R1, LSL #1] ; R1 is the index, PC is used as base of the branch table

BranchTable_H
DCI ((CaseA - BranchTable_H)/2) ; CaseA offset calculation
DCI ((CaseB - BranchTable_H)/2) ; CaseB offset calculation
DCI ((CaseC - BranchTable_H)/2) ; CaseC offset calculation

CaseA
; an instruction sequence follows
CaseB
; an instruction sequence follows
CaseC
; an instruction sequence follows

</table>
3.9.1  BKPT

Breakpoint.

Syntax

BKPT # imm

where:
- ‘imm’ is an expression evaluating to an integer in the range 0-255 (8-bit value).

Operation

The BKPT instruction causes the processor to enter Debug state. Debug tools can use this to investigate system state when the instruction at a particular address is reached.

imm is ignored by the processor. If required, a debugger can use it to store additional information about the breakpoint.

The BKPT instruction can be placed inside an IT block, but it executes unconditionally, unaffected by the condition specified by the IT instruction.

Condition flags

This instruction does not change the flags.

Examples

BKPT 0xAB ; Breakpoint with immediate value set to 0xAB (debugger can extract the immediate value by locating it using the PC)

3.9.2  CPS

Change Processor State.

Syntax

CPS effect iflags

where:
- ‘effect’ is one of:
  - IE: Clears the special purpose register.
  - ID: Sets the special purpose register.
- ‘iflags’ is a sequence of one or more flags:
  - i: Set or clear PRIMASK.
  - f: Set or clear FAULTMASK.
**Operation**

CPS changes the PRIMASK and FAULTMASK special register values. See *Exception mask registers on page 20* for more information about these registers.

**Restrictions**

The restrictions are:

- Use CPS only from privileged software, it has no effect if used in unprivileged software
- CPS cannot be conditional and so must not be used inside an IT block.

**Condition flags**

This instruction does not change the condition flags.

**Examples**

CPSID i ; Disable interrupts and configurable fault handlers (set PRIMASK)
CPSID f ; Disable interrupts and all fault handlers (set FAULTMASK)
CPSIE i ; Enable interrupts and configurable fault handlers (clear PRIMASK)
CPSIE f ; Enable interrupts and fault handlers (clear FAULTMASK)

### 3.9.3 DMB

Data Memory Barrier.

**Syntax**

DMB{cond}

where:

- ‘cond’ is an optional condition code, see *Conditional execution on page 58*.

**Operation**

DMB acts as a data memory barrier. It ensures that all explicit memory accesses that appear, in program order, before the DMB instruction are completed before any explicit memory accesses that appear, in program order, after the DMB instruction. DMB does not affect the ordering or execution of instructions that do not access memory.

**Condition flags**

This instruction does not change the flags.

**Examples**

DMB ; Data Memory Barrier

### 3.9.4 DSB

Data Synchronization Barrier.

**Syntax**

DSB{cond}
where:

- "cond" is an optional condition code, see *Conditional execution on page 58.*

**Operation**

DSB acts as a special data synchronization memory barrier. Instructions that come after the DSB, in program order, do not execute until the DSB instruction completes. The DSB instruction completes when all explicit memory accesses before it complete.

**Condition flags**

This instruction does not change the flags.

**Examples**

```
DSB ; Data Synchronisation Barrier
```

### 3.9.5 ISB

Instruction Synchronization Barrier.

**Syntax**

```
ISB{cond}
```

where:

- "cond" is an optional condition code, see *Conditional execution on page 58.*

**Operation**

ISB acts as an instruction synchronization barrier. It flushes the pipeline of the processor, so that all instructions following the ISB are fetched from cache or memory again, after the ISB instruction has been completed.

**Condition flags**

This instruction does not change the flags.

**Examples**

```
ISB ; Instruction Synchronisation Barrier
```

### 3.9.6 MRS

Move the contents of a special register to a general-purpose register.

**Syntax**

```
MRS{cond} Rd, spec_reg
```
where:

- ‘cond’ is an optional condition code, see *Conditional execution on page 58*.
- ‘Rd’ is the destination register.
- ‘spec_reg’ can be any of: APSR, IPSR, EPSR, IEPSR, IAPSR, EAPSR, PSR, MSP, PSP, PRIMASK, BASEPRI, BASEPRI_MAX, FAULTMASK, or CONTROL.

**Operation**

Use MRS in combination with MSR as part of a read-modify-write sequence for updating a PSR, for example to clear the Q flag.

In process swap code, the programmers model state of the process being swapped out must be saved, including relevant PSR contents. Similarly, the state of the process being swapped in must also be restored. These operations use MRS in the state-saving instruction sequence and MSR in the state-restoring instruction sequence.

BASEPRI_MAX is an alias of BASEPRI when used with the MRS instruction.

See *MSR on page 102*.

**Restrictions**

Rd must not be SP and must not be PC.

**Condition flags**

This instruction does not change the flags.

**Examples**

```
MRS R0, PRIMASK ; Read PRIMASK value and write it to R0
```

### 3.9.7 MSR

Move the contents of a general-purpose register into the specified special register.

**Syntax**

```
MSR{cond} spec_reg, Rn
```

where:

- ‘cond’ is an optional condition code, see *Conditional execution on page 58*.
- ‘Rn’ is the source register.
- ‘spec_reg’ can be any of: APSR, IPSR, EPSR, IEPSR, IAPSR, EAPSR, PSR, MSP, PSP, PRIMASK, BASEPRI, BASEPRI_MAX, FAULTMASK, or CONTROL.

**Operation**

The register access operation in MSR depends on the privilege level. Unprivileged software can only access the APSR, see *Table 4: APSR bit definitions on page 18*. Privileged software can access all special registers.

In unprivileged software writes to unallocated or execution state bits in the PSR are ignored.
When you write to BASEPRI_MAX, the instruction writes to BASEPRI only if either:

- $Rn$ is non-zero and the current BASEPRI value is 0
- $Rn$ is non-zero and less than the current BASEPRI value.

See MRS on page 101.

Restrictions

$Rn$ must not be SP and must not be PC.

Condition flags

This instruction updates the flags explicitly based on the value in $Rn$.

Examples

MRS  CONTROL, R1 ; Read R1 value and write it to the CONTROL register

3.9.8 NOP

No Operation.

Syntax

NOP($cond$)

where:

- ‘$cond$’ is an optional condition code, see Conditional execution on page 58.

Operation

NOP does nothing. NOP is not necessarily a time-consuming NOP. The processor might remove it from the pipeline before it reaches the execution stage.

Use NOP for padding, for example to place the following instruction on a 64-bit boundary.

Condition flags

This instruction does not change the flags.

Examples

NOP ; No operation

3.9.9 SEV

Send Event.

Syntax

SEV($cond$)

where:

- ‘$cond$’ is an optional condition code, see Conditional execution on page 58.
Operation
SEV is a hint instruction that causes an event to be signaled to all processors within a multiprocessor system. It also sets the local event register to 1, see *Power management on page 43.*

Condition flags
This instruction does not change the flags.

Examples
SEV ; Send Event

3.9.10 SVC
Supervisor Call.

Syntax

\[ \text{SVC}(\text{cond}) \# \text{imm} \]

where:
- ‘cond’ is an optional condition code, see *Conditional execution on page 58.*
- ‘imm’ is an expression evaluating to an integer in the range 0-255 (8-bit value).

Operation
The SVC instruction causes the SVC exception. \( \text{imm} \) is ignored by the processor. If required, it can be retrieved by the exception handler to determine what service is being requested.

Condition flags
This instruction does not change the flags.

Examples
SVC 0x32 ; Supervisor Call (SVC handler can extract the immediate value \( \text{imm} \) by locating it via the stacked PC)

3.9.11 WFE
Wait For Event.

Syntax

\[ \text{WFE}(\text{cond}) \]

where:
- ‘cond’ is an optional condition code, see *Conditional execution on page 58.*

Operation
WFE is a hint instruction.
If the event register is 0, WFE suspends execution until one of the following events occurs:

- An exception, unless masked by the exception mask registers or the current priority level
- An exception enters the Pending state, if SEVONPEND in the System Control Register is set
- A Debug Entry request, if Debug is enabled
- An event signaled by a peripheral or another processor in a multiprocessor system using the SEV instruction.

If the event register is 1, WFE clears it to 0 and returns immediately.

For more information see *Power management on page 43*.

**Condition flags**

This instruction does not change the flags.

**Examples**

```
WFE ; Wait for event
```

### 3.9.12 WFI

Wait for Interrupt.

**Syntax**

`WFI{cond}`

where:

- ‘cond’ is an optional condition code, see *Conditional execution on page 58*.

**Operation**

WFI is a hint instruction that suspends execution until one of the following events occurs:

- An exception
- A Debug Entry request, regardless of whether Debug is enabled.

**Condition flags**

This instruction does not change the flags.

**Examples**

```
WFI ; Wait for interrupt
```
4 Core peripherals

4.1 About the STM32 core peripherals

The address map of the Private peripheral bus (PPB) is:

<table>
<thead>
<tr>
<th>Address</th>
<th>Core peripheral</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0xE000E010-0xE000E01F</td>

</tr>
</tbody>
</table>

1. Software can read the MPU Type Register at 0xE000ED90 to test for the presence of a memory protection unit (MPU).

In register descriptions:
- The required privilege gives the privilege level required to access the register, as follows:
  - Privileged Only privileged software can access the register.
  - Unprivileged Both unprivileged and privileged software can access the register.

4.2 Memory protection unit (MPU)

This section describes the Memory protection unit (MPU) which is implemented in some STM32 microcontrollers. Refer to the corresponding device datasheet to see if the MPU is present in the STM32 type you are using.

The MPU divides the memory map into a number of regions, and defines the location, size, access permissions, and memory attributes of each region. It supports:
- Independent attribute settings for each region
- Overlapping regions
- Export of memory attributes to the system.

The memory attributes affect the behavior of memory accesses to the region. The Cortex-M3 MPU defines:
- Eight separate memory regions, 0-7
- A background region.

When memory regions overlap, a memory access is affected by the attributes of the region with the highest number. For example, the attributes for region 7 take precedence over the attributes of any region that overlaps region 7.

The background region has the same memory access attributes as the default memory map, but is accessible from privileged software only.
The Cortex-M3 MPU memory map is unified. This means instruction accesses and data accesses have same region settings.

If a program accesses a memory location that is prohibited by the MPU, the processor generates a memory management fault. This causes a fault exception, and might cause termination of the process in an OS environment.

In an OS environment, the kernel can update the MPU region setting dynamically based on the process to be executed. Typically, an embedded OS uses the MPU for memory protection.

Configuration of MPU regions is based on memory types, see Section 2.2.1: Memory regions, types and attributes on page 26.

Table 34 shows the possible MPU region attributes.

### Table 34. Memory attributes summary

#### 4.2.1 MPU access permission attributes

This section describes the MPU access permission attributes. The access permission bits, TEX, C, B, S, AP, and XN, of the MPU_RASR register, control access to the corresponding memory region. If an access is made to an area of memory without the required permissions, then the MPU generates a permission fault.

Table 35 shows the encodings for the TEX, C, B, and S access permission bits.
Table 35. TEX, C, B, and S encoding

</tr>
</tbody>
</table>
4.2.2 MPU mismatch

When an access violates the MPU permissions, the processor generates a memory management fault, see Section 2.1.4: Exceptions and interrupts on page 23. The MMFSR indicates the cause of the fault. See Section 4.4.11: Memory management fault address register (SCB_MMFAR) on page 146 for more information.

4.2.3 Updating an MPU region

To update the attributes for an MPU region, update the MPU_RNR, MPU_RBAR and MPU_RASR registers. You can program each register separately, or use a multiple-word write to program all of these registers. You can use the MPU_RBAR and MPU_RASR aliases to program up to four regions simultaneously using an STM instruction.

Updating an MPU region using separate words

Simple code to configure one region:

```assembly
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPU_RNR         ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]      ; Region Number
STR R4, [R0, #0x4]      ; Region Base Address
STRH R2, [R0, #0x8]     ; Region Size and Enable
STRH R3, [R0, #0xA]     ; Region Attribute
```

Disable a region before writing new region settings to the MPU if you have previously enabled the region being changed. For example:

```assembly
; R1 = region number
; R2 = size/enable
; R3 = attributes
; R4 = address
LDR R0,=MPU_RNR         ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]      ; Region Number
BIC R2, R2, #1           ; Disable
STRH R2, [R0, #0x8]     ; Region Size and Enable
STR R4, [R0, #0x4]      ; Region Base Address
STRH R3, [R0, #0xA]     ; Region Attribute
ORR R2, #1               ; Enable
STRH R2, [R0, #0x8]     ; Region Size and Enable
```

Table 37. AP encoding (continued)

<table>
<thead>
<tr>

</tr>
<tr>
<td>111</td>
<td>RO</td>
<td>RO</td>
<td>Read only, by privileged or unprivileged software</td>
</tr>
</tbody>
</table>
Software must use memory barrier instructions:

- Before MPU setup if there might be outstanding memory transfers, such as buffered writes, that might be affected by the change in MPU settings
- After MPU setup if it includes memory transfers that must use the new MPU settings.

However, memory barrier instructions are not required if the MPU setup process starts by entering an exception handler, or is followed by an exception return, because the exception entry and exception return mechanism cause memory barrier behavior.

Software does not need any memory barrier instructions during MPU setup, because it accesses the MPU through the PPB, which is a Strongly-Ordered memory region.

For example, if you want all of the memory access behavior to take effect immediately after the programming sequence, use a DSB instruction and an ISB instruction. A DSB is required after changing MPU settings, such as at the end of context switch. An ISB is required if the code that programs the MPU region or regions is entered using a branch or call. If the programming sequence is entered using a return from exception, or by taking an exception, then you do not require an ISB.

Updating an MPU region using multi-word writes

You can program directly using multi-word writes, depending on how the information is divided. Consider the following reprogramming:

```assembly
; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPU_RNR    ; 0xE000ED98, MPU region number register
STR R1, [R0, #0x0]  ; Region Number
STR R2, [R0, #0x4]  ; Region Base Address
STR R3, [R0, #0x8]  ; Region Attribute, Size and Enable
```

Use an STM instruction to optimize this:

```assembly
; R1 = region number
; R2 = address
; R3 = size, attributes in one
LDR R0, =MPU_RNR    ; 0xE000ED98, MPU region number register
STM R0, {R1-R3}     ; Region Number, address, attribute, size and enable
```

You can do this in two words for pre-packed information. This means that the RBAR contains the required region number and had the VALID bit set to 1, see MPU region base address register (MPU_RBAR) on page 115. Use this when the data is statically packed, for example in a boot loader:

```assembly
; R1 = address and region number in one
; R2 = size and attributes in one
LDR R0, =MPU_RBAR   ; 0xE000ED9C, MPU Region Base register
STR R1, [R0, #0x0]  ; Region base address and region number combined with VALID (bit 4) set to 1
STR R2, [R0, #0x4]  ; Region Attribute, Size and Enable
```

Use an STM instruction to optimize this:

```assembly
; R1 = address and region number in one
; R2 = size and attributes in one
LDR R0, =MPU_RBAR   ; 0xE000ED9C, MPU Region Base register
STM R0, (R1-R2)     ; Region base address, region number and VALID bit, and Region Attribute, Size and Enable
```

Subregions

Regions of 256 bytes or more are divided into eight equal-sized subregions. Set the corresponding bit in the SRD field of the RASR to disable a subregion, see Section 4.2.9:
MPU region attribute and size register (MPU_RASR) on page 117. The least significant bit of SRD controls the first subregion, and the most significant bit controls the last subregion. Disabling a subregion means another region overlapping the disabled range matches instead. If no other enabled region overlaps the disabled subregion the MPU issues a fault.

Regions of 32, 64, and 128 bytes do not support subregions. With regions of these sizes, you must set the SRD field to 0x00, otherwise the MPU behavior is Unpredictable.

**Example of SRD use:**

Two regions with the same base address overlap. Region one is 128KB, and region two is 512KB. To ensure the attributes from region one apply to the first 128KB region, set the SRD field for region two to b00000011 to disable the first two subregions, as the figure shows.

**Figure 18. Subregion example**

</tbody>
</table>

**4.2.4 MPU design hints and tips**

To avoid unexpected behavior, disable the interrupts before updating the attributes of a region that the interrupt handlers might access.

Ensure software uses aligned accesses of the correct size to access MPU registers:

- Except for the RASR, it must use aligned word accesses
- For the RASR it can use byte or aligned halfword or word accesses.

The processor does not support unaligned accesses to MPU registers.

When setting up the MPU, and if the MPU has previously been programmed, disable unused regions to prevent any previous region settings from affecting the new MPU setup.

**Recommended MPU configuration**

The STM32 microcontroller system has only a single processor, so you should program the MPU as follows:
In STM32 implementations, the shareability and cache policy attributes do not affect the system behavior. However, using these settings for the MPU regions can make the application code more portable. The values given are for typical situations.

**Note:** The MPU attributes don't affect DMA data accesses to the memory/peripherals address spaces. Therefore, in order to protect the memory areas against inadvertent DMA accesses, the MPU must control the SW/CPU access to the DMA registers.

### 4.2.5 MPU type register (MPU_TYPER)

- **Address offset:** 0x00
- **Reset value:** 0x0000 0800
- **Required privilege:** Privileged

The MPU_TYPER register indicates whether the MPU is present, and if so, how many regions it supports.

Bits 31:24 Reserved, forced by hardware to 0.

Bits 23:16 **IREGION[7:0]:** Number of MPU instruction regions.

These bits indicate the number of supported MPU instruction regions.

Always contains 0x00. The MPU memory map is unified and is described by the DREGION field.
4.2.6 MPU control register (MPU_CR)

Address offset: 0x04
Reset value: 0x0000 0000
Required privilege: Privileged

The MPU_CR register:
- Enables the MPU
- Enables the default memory map background region
- Enables use of the MPU when in the hard fault, Non-maskable Interrupt (NMI), and FAULTMASK escalated handlers.

When ENABLE and PRIVDEFENA are both set to 1:
- For privileged accesses, the default memory map is as described in Section 2.2: Memory model on page 25. Any access by privileged software that does not address an enabled memory region behaves as defined by the default memory map.
- Any access by unprivileged software that does not address an enabled memory region causes a memory management fault.

XN and Strongly-ordered rules always apply to the System Control Space regardless of the value of the ENABLE bit.

When the ENABLE bit is set to 1, at least one region of the memory map must be enabled for the system to function unless the PRIVDEFENA bit is set to 1. If the PRIVDEFENA bit is set to 1 and no regions are enabled, then only privileged software can operate.

When the ENABLE bit is set to 0, the system uses the default memory map. This has the same memory attributes as if the MPU is not implemented, see Table 12: Memory access behavior on page 27. The default memory map applies to accesses from both privileged and unprivileged software.

When the MPU is enabled, accesses to the System Control Space and vector table are always permitted. Other areas are accessible based on regions and whether PRIVDEFENA is set to 1.

Unless HFNMIENA is set to 1, the MPU is not enabled when the processor is executing the handler for an exception with priority –1 or –2. These priorities are only possible when handling a hard fault or NMI exception, or when FAULTMASK is enabled. Setting the HFNMIENA bit to 1 enables the MPU when operating with these two priorities.
4.2.7 MPU region number register (MPU_RNR)

Address offset: 0x08
Reset value: 0x0000 0000
Required privilege: Privileged

The MPU_RNR register selects which memory region is referenced by the MPU_RBAR and MPU_RASR registers.

<th>ENABLE</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>rw</td>
<td>rw</td>
<td>rw</td>
</tr>
</tbody>
</table>

Bits 31:0 Reserved, forced by hardware to 0.

Bit 2 PRIVDEFEA: Enable privileged software access to default memory map.

0: If the MPU is enabled, disables use of the default memory map. Any memory access to a location not covered by any enabled region causes a fault.

1: If the MPU is enabled, enables use of the default memory map as a background region for privileged software accesses.

Note: When enabled, the background region acts as if it is region number -1. Any region that is defined and enabled has priority over this default map.

Note: If the MPU is disabled, the processor ignores this bit.

Bit 1 HFNMIENA: Enables the operation of MPU during hard fault, NMI, and FAULTMASK handlers.

When the MPU is enabled:

0: MPU is disabled during hard fault, NMI, and FAULTMASK handlers, regardless of the value of the ENABLE bit

1: The MPU is enabled during hard fault, NMI, and FAULTMASK handlers.

Note: When the MPU is disabled, if this bit is set to 1 the behavior is unpredictable.

Bit 0 ENABLE: Enables the MPU

0: MPU disabled

1: MPU enabled
4.2.8 MPU region base address register (MPU_RBAR)

Address offset: 0x0C
Reset value: 0x0000 0000
Required privilege: Privileged

The MPU_RBAR register defines the base address of the MPU region selected by the MPU_RNR register, and can update the value of the MPU_RNR register.

Write to the MPU_RBAR register with the VALID bit set to 1 to change the current region number and update the MPU_RNR register.

```
+----------------+-----------------+
| 31 30 29 28 27 26 25 24 23 22 21 20 19 18 17 16 |
|   ADDR[31:N]...   |                |
|                |                |
|                |                |
|                |                |
+----------------+-----------------+
| 15 14 13 12 11 10  9  8  7  6  5  4  3  2  1  0 |
|    ...ADDR[31:N]    | VALID | REGION[3:0] |
|                |     rw |         rw |
+----------------+-----------------+
```
Bits 31:N  **ADDR[31:N]**: Region base address field

The value of N depends on the region size.

The region size, as specified by the SIZE field in the RASR, defines the value of N:

\[ N = \log_2(\text{Region size in bytes}) \]

If the region size is configured to 4 GB, in the MPU_RASR register, there is no valid ADDR field. In this case, the region occupies the complete memory map, and the base address is 0x00000000.

The base address is aligned to the size of the region. For example, a 64 KB region must be aligned on a multiple of 64 KB, for example, at 0x00010000 or 0x00020000.

Bits N-1:5  Reserved, forced by hardware to 0.

Bit 4  **VALID**: MPU region number valid

Write:

- 0: MPU_RNR register not changed, and the processor:
  - Updates the base address for the region specified in the RNR
  - Ignores the value of the REGION field
- 1: the processor:
  - updates the value of the RNR to the value of the REGION field
  - updates the base address for the region specified in the REGION field.

Read:

Always read as zero.

Bits 3:0  **REGION[3:0]**: MPU region field

For the behavior on writes, see the description of the VALID field.

On reads, returns the current region number, as specified by the MPU_RNR register.
4.2.9 MPU region attribute and size register (MPU_RASR)

Address offset: 0x10
Reset value: 0x0000 0000
Required privilege: Privileged

The MPU_RASR register defines the region size and memory attributes of the MPU region specified by the MPU_RNR, and enables that region and any subregions.

MPU_RASR is accessible using word or halfword accesses:
- The most significant halfword holds the region attributes
- The least significant halfword holds the region size and the region and subregion enable bits.

</tr>
</tbody>
</table>

Bits 31:29 Reserved, forced by hardware to 0.

Bit 28 **XN**: Instruction access disable bit:
- 0: Instruction fetches enabled
- 1: Instruction fetches disabled.

Bit 27 Reserved, forced by hardware to 0.

Bits 26:24 **AP[2:0]**: Access permission
For information about access permission, see Section 4: Core peripherals
For the description of the encoding of the AP bits refer to Table 37 on page 108.

Bits 23:22 Reserved, forced by hardware to 0.

Bits 21:19 **TEX[2:0]**: memory attribute
For the description of the encoding of the TEX bits refer to Table 35 on page 108

Bit 18 **S**: Shareable memory attribute
For the description of the encoding of the S bits refer to Table 35 on page 108

Bit 17 **C**: memory attribute
Bit 16 **B**: memory attribute

Bits 15:8 **SRD**: Subregion disable bits.
For each bit in this field:
- 0: corresponding sub-region is enabled
- 1: corresponding sub-region is disabled
See Subregions on page 110 for more information.
Region sizes of 128 bytes and less do not support subregions. When writing the attributes for such a region, write the SRD field as 0x00.
The SIZE field defines the size of the MPU memory region specified by the MPU_RNR register as follows:

\[(\text{Region size in bytes}) = 2(\text{SIZE}+1)\]

The smallest permitted region size is 32B, corresponding to a SIZE value of 4. Table 4-45 gives example SIZE values, with the corresponding region size and value of N in the RBAR.

1. In the MPU_RBAR register see Section 4.2.8 on page 115
4.3 Nested vectored interrupt controller (NVIC)

This section describes the Nested Vectored Interrupt Controller (NVIC) and the registers it uses. The NVIC supports:

- up to 81 interrupts (depends on the STM32 device type, refer to the datasheets)
- A programmable priority level of 0-15 for each interrupt. A higher level corresponds to a lower priority, so level 0 is the highest interrupt priority
- Level and pulse detection of interrupt signals
- Dynamic reprioritization of interrupts
- Grouping of priority values into group priority and subpriority fields
- Interrupt tail-chaining
- An external Non-maskable interrupt (NMI)

The processor automatically stacks its state on exception entry and unstacks this state on exception exit, with no instruction overhead. This provides low latency exception handling. The hardware implementation of the NVIC registers is:

4.3.1 The CMSIS mapping of the Cortex-M3 NVIC registers

To improve software efficiency, the CMSIS simplifies the NVIC register presentation. In the CMSIS:

- The Set-enable, Clear-enable, Set-pending, Clear-pending and Active Bit registers map to arrays of 32-bit integers, so that:
  - The array ISER[0] to ISER[2] corresponds to the registers ISER0-ISER2
  - The array ICER[0] to ICER[2] corresponds to the registers ICER0-ICER2
  - The array ISPR[0] to ISPR[2] corresponds to the registers ISPR0-ISPR2
  - The array ICPR[0] to ICPR[2] corresponds to the registers ICPR0-ICPR2
  - The array IABR[0] to IABR[2] corresponds to the registers IABR0-IABR2.

- The 8-bit fields of the Interrupt Priority Registers map to an array of 8-bit integers, so that the array IP[0] to IP[67] corresponds to the registers IPR0-IPR67, and the array entry IP[n] holds the interrupt priority for interrupt n.

The CMSIS provides thread-safe code that gives atomic access to the Interrupt Priority Registers. For more information see the description of the NVIC_SetPriority function in NVIC programming hints on page 128. Table 41 shows how the interrupts, or IRQ numbers, map onto the interrupt registers and corresponding CMSIS variables that have one bit per interrupt.

Table 41. Mapping of interrupts to the interrupt variables

<table>
<thead>
<tr>
<th>Interrupts</th>

<td>rs</td>
</tr>
</tbody>
</table>

Bits 31:0 SETENA[31:0]: Interrupt set-enable bits.

Write:
0: No effect
1: Enable interrupt

Read:
0: Interrupt disabled
1: Interrupt enabled.

See Table 41: Mapping of interrupts to the interrupt variables on page 120 for the correspondence of interrupts to each register bit.

If a pending interrupt is enabled, the NVIC activates the interrupt based on its priority. If an interrupt is not enabled, asserting its interrupt signal changes the interrupt state to pending, but the NVIC never activates the interrupt, regardless of its priority.
4.3.3 Interrupt clear-enable registers (NVIC_ICERx)

Address offset: 0x00 - 0x0B
Reset value: 0x0000 0000
Required privilege: Privileged

The ICER0-ICER2 registers disable interrupts, and show which interrupts are enabled.

<table>

<table>
<thead>
<tr>
<th>15:0</th>
</tr>
</thead>
<tbody>
<tr>
<td>CLREN[15:0]</td>
</tr>
<tr>
<td>rc_w1</td>
</tr>
</tbody>
</table>

Bits 31:0 CLREN[31:0]: Interrupt clear-enable bits.

Write:
0: No effect
1: Disable interrupt

Read:
0: Interrupt disabled
1: Interrupt enabled.

See Table 41: Mapping of interrupts to the interrupt variables on page 120 for the correspondence of interrupts to each register bit.
4.3.4 Interrupt set-pending registers (NVIC_ISPRx)

Address offset: 0x00 - 0x0B
Reset value: 0x0000 0000
Required privilege: Privileged

The ISPR0-ISPR2 registers force interrupts into the pending state, and show which interrupts are pending.

<table>
<thead>
<tr>
<th>Bits 31:0 SETPEND[31:0]: Interrupt set-pending bits</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Write:</strong></td>
</tr>
<tr>
<td>0: No effect</td>
</tr>
<tr>
<td>1: Changes interrupt state to pending</td>

<tr>
<td><strong>Read:</strong></td>
</tr>
<tr>
<td>0: Interrupt is not pending</td>
</tr>
<tr>
<td>1: Interrupt is pending</td>
</tr>
</tbody>
</table>

Writing 1 to the ISPR bit corresponding to a disabled interrupt:

- sets the state of that interrupt to pending.

Writing 1 to the ISPR bit corresponding to an interrupt that is pending:

- has no effect.
4.3.5 Interrupt clear-pending registers (NVIC_ICPRx)

Address offset: 0x00 - 0x0B
Reset value: 0x0000 0000
Required privilege: Privileged

The ICPR0-ICPR2 registers remove the pending state from interrupts, and show which interrupts are pending.

<table>
<thead>
<tr>

</tr>
</thead>
<tbody>
<tr>
<td>CLRPEND[15:0]</td>
</tr>
<tr>
<td>rc_w1</td>
</tr>
</tbody>
</table>

Bits 31:0 CLRPEND[31:0]: Interrupt clear-pending bits

Write:
- 0: No effect
- 1: Removes the pending state of an interrupt

Read:
- 0: Interrupt is not pending
- 1: Interrupt is pending

See Table 41: Mapping of interrupts to the interrupt variables on page 120 for the correspondence of interrupts to each register bit.

Writing 1 to an ICPR bit does not affect the active state of the corresponding interrupt.
4.3.6 Interrupt active bit registers (NVIC_IABRx)

Address offset: 0x00- 0x0B
Reset value: 0x0000 0000
Required privilege: Privileged

The IABR0-IABR2 registers indicate which interrupts are active.

The bit assignments are:

<table>
<thead>
<tr>
<th>31</th>
<th>30</th>
<th>29</th>
<th>28</th>
<th>27</th>
<th>26</th>
<th>25</th>

</tr>
</tbody>
</table>

Bits 31:0 ACTIVE[31:0]: Interrupt active flags
0: Interrupt not active
1: Interrupt active

See Table 41: Mapping of interrupts to the interrupt variables on page 120 for the correspondence of interrupts to each register bit.
A bit reads as 1 if the status of the corresponding interrupt is active or active and pending.
4.3.7 Interrupt priority registers (NVIC_IPRx)

Address offset: 0x000- 0x0B
Reset value: 0x0000 0000
Required privilege: Privileged

The IPR0-IPR16 registers provide a 4-bit priority field for each interrupt. These registers are byte-accessible. Each register holds four priority fields, that map to four elements in the CMSIS interrupt priority array IP[0] to IP[67], as shown in Figure 19.

Figure 19. NVIC_IPRx register mapping

Table 42. IPR bit assignments

<table>
<thead>
<tr>
<th>Bits</th>
<th>Name</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:24] Priority, byte offset 3</td>
<td>Each priority field holds a priority value, 0-255. The lower the value, the greater the priority of the corresponding interrupt. The processor implements only bits[7:4] of each field, bits[3:0] read as zero and ignore writes.</td>
<td></td>
</tr>
<tr>
<td>[23:16] Priority, byte offset 2</td>

<td></td>
</tr>
</tbody>
</table>

See The CMSIS mapping of the Cortex-M3 NVIC registers on page 120 for more information about the IP[0] to IP[67] interrupt priority array, that provides the software view of the interrupt priorities.

Find the IPR number and byte offset for interrupt N as follows:

- The corresponding IPR number, M, is given by \( M = \frac{N}{4} \)
- The byte offset of the required Priority field in this register is \( N \mod 4 \), where:
  - byte offset 0 refers to register bits[7:0]
  - byte offset 1 refers to register bits[15:8]
  - byte offset 2 refers to register bits[23:16]
  - byte offset 3 refers to register bits[31:24].
4.3.8 Software trigger interrupt register (NVIC_STIR)

Address offset: 0xE00
Reset value: 0x0000 0000

Required privilege: When the USERSETMPEND bit in the SCR is set to 1, unprivileged software can access the STIR, see Section 4.4.5: System control register (SCB_SCR). Only privileged software can enable un privileged access to the STIR.

Reserved

INTID[8:0]

Bits 31:9 Reserved, must be kept cleared.

Bits 8:0 INTID[8:0] Software generated interrupt ID
Write to the STIR to generate a Software Generated Interrupt (SGI). The value to be written is the Interrupt ID of the required SGI, in the range 0-239. For example, a value of 0b0000000011 specifies interrupt IRQ3.

4.3.9 Level-sensitive and pulse interrupts

STM32 interrupts are both level-sensitive and pulse-sensitive. Pulse interrupts are also described as edge-triggered interrupts.

A level-sensitive interrupt is held asserted until the peripheral deasserts the interrupt signal. Typically this happens because the ISR accesses the peripheral, causing it to clear the interrupt request. A pulse interrupt is an interrupt signal sampled synchronously on the rising edge of the processor clock. To ensure the NVIC detects the interrupt, the peripheral must assert the interrupt signal for at least one clock cycle, during which the NVIC detects the pulse and latches the interrupt.

When the processor enters the ISR, it automatically removes the pending state from the interrupt, see Hardware and software control of interrupts. For a level-sensitive interrupt, if the signal is not deasserted before the processor returns from the ISR, the interrupt becomes pending again, and the processor must execute its ISR again. This means that the peripheral can hold the interrupt signal asserted until it no longer needs servicing.

Hardware and software control of interrupts

The Cortex-M3 latches all interrupts. A peripheral interrupt becomes pending for one of the following reasons:

- The NVIC detects that the interrupt signal is HIGH and the interrupt is not active
- The NVIC detects a rising edge on the interrupt signal
- Software writes to the corresponding interrupt set-pending register bit, see Section 4.3.4: Interrupt set-pending registers (NVIC_ISPRx), or to the STIR to make an SGI pending, see Section 4.3.8: Software trigger interrupt register (NVIC_STIR).
A pending interrupt remains pending until one of the following:

- The processor enters the ISR for the interrupt. This changes the state of the interrupt from pending to active. Then:
  - For a level-sensitive interrupt, when the processor returns from the ISR, the NVIC samples the interrupt signal. If the signal is asserted, the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, the NVIC continues to monitor the interrupt signal, and if this is pulsed the state of the interrupt changes to pending and active. In this case, when the processor returns from the ISR the state of the interrupt changes to pending, which might cause the processor to immediately re-enter the ISR. If the interrupt signal is not pulsed while the processor is in the ISR, when the processor returns from the ISR the state of the interrupt changes to inactive.

- Software writes to the corresponding interrupt clear-pending register bit.
  - For a level-sensitive interrupt, if the interrupt signal is still asserted, the state of the interrupt does not change. Otherwise, the state of the interrupt changes to inactive.
  - For a pulse interrupt, state of the interrupt changes to:
    - Inactive, if the state was pending
    - Active, if the state was active and pending.

4.3.10 NVIC design hints and tips

Ensure software uses correctly aligned register accesses. The processor does not support unaligned accesses to NVIC registers. See the individual register descriptions for the supported access sizes.

A interrupt can enter pending state even it is disabled.

Before programming VTOR to relocate the vector table, ensure the vector table entries of the new vector table are setup for fault handlers, NMI and all enabled exception like interrupts. For more information see Section 4.4.3: Vector table offset register (SCB_VTOR) on page 133.

NVIC programming hints

Software uses the CPSIE I and CPSID I instructions to enable and disable interrupts. The CMSIS provides the following intrinsic functions for these instructions:

```c
void __disable_irq(void) // Disable Interrupts
void __enable_irq(void) // Enable Interrupts
```

In addition, the CMSIS provides a number of functions for NVIC control, including:

<table>
<thead>
<tr>
<th>CMSIS interrupt control function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void NVIC_SetPriorityGrouping(uint32_t priority_grouping)</td>
<td>Set the priority grouping</td>
</tr>
<tr>
<td>void NVIC_EnableIRQ(IRQn_t IRQn)</td>
<td>Enable IRQn</td>
</tr>
<tr>
<td>void NVIC_DisableIRQ(IRQn_t IRQn)</td>
<td>Disable IRQn</td>
</tr>
<tr>
<td>uint32_t NVIC_GetPendingIRQ (IRQn_t IRQn)</td>
<td>Return true (IRQ-Number) if IRQn is pending</td>
</tr>
</tbody>
</table>
Table 43. CMSIS functions for NVIC control (continued)

<table>
<thead>
<tr>
<th>CMSIS interrupt control function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>void NVIC_SetPendingIRQ (IRQn_t IRQn)</td>
<td>Set IRQn pending</td>
</tr>
<tr>
<td>void NVIC_ClearPendingIRQ (IRQn_t IRQn)</td>
<td>Clear IRQn pending status</td>
</tr>
<tr>
<td>uint32_t NVIC_GetActive (IRQn_t IRQn)</td>
<td>Return the IRQ number of the active interrupt</td>
</tr>
<tr>
<td>void NVIC_SetPriority (IRQn_t IRQn, uint32_t priority)</td>
<td>Set priority for IRQn</td>
</tr>
<tr>
<td>uint32_t NVIC_GetPriority (IRQn_t IRQn)</td>
<td>Read priority of IRQn</td>
</tr>
<tr>
<td>void NVIC_SystemReset (void)</td>
<td>Reset the system</td>
</tr>
</tbody>
</table>

For more information about these functions see the CMSIS documentation.

4.3.11 NVIC register map

The table provides shows the NVIC register map and reset values. The base address of the main NVIC register block is 0xE000E100. The NVIC_STIR register is located in a separate block at 0xE000EF00.

Table 44. NVIC register map and reset values

4.4 System control block (SCB)

The System control block (SCB) provides system implementation information, and system control. This includes configuration, control, and reporting of the system exceptions. The CMSIS mapping of the Cortex-M3 SCB registers

To improve software efficiency, the CMSIS simplifies the SCB register presentation. In the CMSIS, the byte array SHP[0] to SHP[12] corresponds to the registers SHPR1-SHPR3.

4.4.1 CPUID base register (SCB_CPUID)

Address offset: 0x00
Reset value: 0x411F C231
Required privilege: Privileged

The CPUID register contains the processor part number, version, and implementation information.

Table 44. NVIC register map and reset values (continued)
4.4.2 Interrupt control and state register (SCB_ICSR)

Address offset: 0x04
Reset value: 0x0000 0000
Required privilege: Privileged

The ICSR:

- Provides:
  - A set-pending bit for the Non-Maskable Interrupt (NMI) exception
  - Set-pending and clear-pending bits for the PendSV and SysTick exceptions

- Indicates:
  - The exception number of the exception being processed
  - Whether there are preempted active exceptions
  - The exception number of the highest priority pending exception
  - Whether any interrupts are pending.

Caution: When you write to the ICSR, the effect is unpredictable if you:

- Write 1 to the PENDSVSET bit and write 1 to the PENDSVCLR bit
- Write 1 to the PENDSTSET bit and write 1 to the PENDSTCLR bit.
Bit 31  **NMIPENDSET**: NMI set-pending bit.

**Write:**
- 0: No effect
- 1: Change NMI exception state to pending.

**Read:**
- 0: NMI exception is not pending
- 1: NMI exception is pending

Because NMI is the highest-priority exception, normally the processor enters the NMI exception handler as soon as it registers a write of 1 to this bit, and entering the handler clears this bit to 0. A read of this bit by the NMI exception handler returns 1 only if the NMI signal is reasserted while the processor is executing that handler.

Bits 30:29  Reserved, must be kept cleared

Bit 28  **PENDSVSET**: PendSV set-pending bit.

**Write:**
- 0: No effect
- 1: Change PendSV exception state to pending.

**Read:**
- 0: PendSV exception is not pending
- 1: PendSV exception is pending

Writing 1 to this bit is the only way to set the PendSV exception state to pending.

Bit 27  **PENDSVCLR**: PendSV clear-pending bit.

**Write:**
- 0: No effect
- 1: Removes the pending state from the PendSV exception.

Bit 26  **PENDSTSET**: SysTick exception set-pending bit.

**Write:**
- 0: No effect
- 1: Change SysTick exception state to pending

**Read:**
- 0: SysTick exception is not pending
- 1: SysTick exception is pending

Bit 25  **PENDSTCLR**: SysTick exception clear-pending bit.

**Write:**
- 0: No effect
- 1: Removes the pending state from the SysTick exception.

This bit is write-only. On a register read its value is unknown.

Bit 24  Reserved, must be kept cleared.

Bit 23  This bit is reserved for Debug use and reads-as-zero when the processor is not in Debug.

Bit 22  **ISRPENDING**: Interrupt pending flag, excluding NMI and Faults

- 0: Interrupt not pending
- 1: Interrupt pending
Bits 21:12 **VECTPENDING[9:0]** Pending vector
Indicates the exception number of the highest priority pending enabled exception.
- 0: No pending exceptions
- Other values: The exception number of the highest priority pending enabled exception.
The value indicated by this field includes the effect of the BASEPRI and FAULTMASK registers, but not any effect of the PRIMASK register.

Bit 11 **RETOBASE**: Return to base level
Indicates whether there are preempted active exceptions:
- 0: There are preempted active exceptions to execute
- 1: There are no active exceptions, or the currently-executing exception is the only active exception.

Bits 10:9 Reserved, must be kept cleared

Bits 8:0 **VECTACTIVE[8:0]** Active vector
Contains the active exception number:
- 0: Thread mode
- Other values: The exception number(1) of the currently active exception.

Note: Subtract 16 from this value to obtain the IRQ number required to index into the Interrupt Clear-Enable, Set-Enable, Clear-Pending, Set-Pending, or Priority Registers, see Table 5 on page 19.

1. This is the same value as IPSR bits[8:0], see *Interrupt program status register on page 19.*

### 4.4.3 Vector table offset register (SCB_VTOR)

Address offset: 0x08
Reset value: 0x0000 0000
Required privilege: Privileged

<table>
<thead>

<td></td>
</tr>
</tbody>
</table>

Bits 31:30 Reserved, must be kept cleared

Bits 29:11 **TBLOFF[29:9]**: Vector table base offset field.
It contains bits [29:9] of the offset of the table base from memory address 0x00000000. When setting TBLOFF, you must align the offset to the number of exception entries in the vector table. The minimum alignment is 128 words. Table alignment requirements mean that bits[8:0] of the table offset are always zero.

Bit 29 determines whether the vector table is in the code or SRAM memory region.
- 0: Code
- 1: SRAM

Note: Bit 29 is sometimes called the TBLBASE bit.

Bits 10:0 Reserved, must be kept cleared
4.4.4 Application interrupt and reset control register (SCB_AIRCR)

Address offset: 0x0C
Reset value: 0xFA05 0000
Required privilege: Privileged

The AIRCR provides priority grouping control for the exception model, endian status for data accesses, and reset control of the system.

To write to this register, you must write 0x5FA to the VECTKEY field, otherwise the processor ignores the write.

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

**VECTKEYSTAT[15:0]/VECTKEY[15:0]** Register key
- Reads as 0xFA05
- On writes, write 0x5FA to VECTKEY, otherwise the write is ignored.

Bit 15 **ENDIANESS** Data endianness bit
- Reads as 0.
  - 0: Little-endian

Bits 14:11 Reserved, must be kept cleared

Bits 10:8 **PRIGROUP[2:0]**: Interrupt priority grouping field
- This field determines the split of group priority from subpriority, see *Binary point on page 134*.

Bits 7:3 Reserved, must be kept cleared

Bit 2 **SYSRESETREQ** System reset request
- This is intended to force a large system reset of all major components except for debug.
  - This bit reads as 0.
  - 0: No system reset request
  - 1: Asserts a signal to the outer system that requests a reset.

Bit 1 **VECTCLRACTIVE**
- Reserved for Debug use. This bit reads as 0. When writing to the register you must write 0 to this bit, otherwise behavior is unpredictable.

Bit 0 **VECTRESET**
- Reserved for Debug use. This bit reads as 0. When writing to the register you must write 0 to this bit, otherwise behavior is unpredictable.

**Binary point**

The PRIGROUP field indicates the position of the binary point that splits the PRI_n fields in the Interrupt Priority Registers into separate group priority and subpriority fields. *Table 45* shows how the PRIGROUP value controls this split.
Determining preemption of an exception uses only the group priority field, see Section 2.3.6: Interrupt priority grouping on page 38.

4.4.5 System control register (SCB_SCR)

Address offset: 0x10
Reset value: 0x0000 0000
Required privilege: Privileged

The SCR controls features of entry to and exit from low power state.

<table>
<thead>

</tr>
</tbody>
</table>

Bits 31:5 Reserved, must be kept cleared

Bit 4 SEVEO Pend Send Event on Pending bit

When an event or interrupt enters pending state, the event signal wakes up the processor from WFE. If the processor is not waiting for an event, the event is registered and affects the next WFE.

The processor also wakes up on execution of an SEV instruction or an external event

0: Only enabled interrupts or events can wakeup the processor, disabled interrupts are excluded
1: Enabled events and all interrupts, including disabled interrupts, can wakeup the processor.

Bit 3 Reserved, must be kept cleared
4.4.6 Configuration and control register (SCB_CCR)

Address offset: 0x14

Reset value: 0x0000 0200

Required privilege: Privileged

The CCR controls entry to Thread mode and enables:

- The handlers for NMI, hard fault and faults escalated by FAULTMASK to ignore bus faults
- Trapping of divide by zero and unaligned accesses
- Access to the STIR by unprivileged software, see Software trigger interrupt register (NVIC_STIR) on page 127.

<table>
<thead>

<td>Reserved</td>
</tr>
</tbody>
</table>
4.4.7 System handler priority registers (SHPRx)

The SHPR1-SHPR3 registers set the priority level, 0 to 15 of the exception handlers that have configurable priority.

SHPR1-SHPR3 are byte accessible.

The system fault handlers and the priority field and register for each handler are:

<table>
<thead>
<tr>
<th>Handler</th>
<th>Field</th>
<th>Register description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memory management fault</td>
<td>PRI_4</td>
<td>System handler priority register 1 (SCB_SHPR1)</td>
</tr>
<tr>
<td>Bus fault</td>
<td>PRI_5</td>
<td></td>
</tr>
<tr>
<td>Usage fault</td>
<td>PRI_6</td>
<td></td>
</tr>
<tr>
<td>SVC_CALL</td>
<td>PRI_11</td>
<td>System handler priority register 2 (SCB_SHPR2) on page 138</td>
</tr>
<tr>
<td>PendSV</td>
<td>PRI_14</td>
<td>System handler priority register 3 (SCB_SHPR3) on page 139</td>
</tr>
<tr>
<td>SysTick</td>
<td>PRI_15</td>
<td></td>
</tr>
</tbody>
</table>

Each PRI_N field is 8 bits wide, but the processor implements only bits[7:4] of each field, and bits[3:0] read as zero and ignore writes.

Bit 4 DIV_0_TRP
Enables faulting or halting when the processor executes an SDIV or UDIV instruction with a divisor of 0:
- 0: Do not trap divide by 0
- 1: Trap divide by 0.

When this bit is set to 0, a divide by zero returns a quotient of 0.

Bit 3 UNALIGN_TRP
Enables unaligned access traps:
- 0: Do not trap unaligned halfword and word accesses
- 1: Trap unaligned halfword and word accesses.

If this bit is set to 1, an unaligned access generates a usage fault.

Unaligned LDM, STM, LDRD, and STRD instructions always fault irrespective of whether UNALIGN_TRP is set to 1.

Bit 2 Reserved, must be kept cleared

Bit 1 USERSETMPEND
Enables unprivileged software access to the STIR, see Software trigger interrupt register (NVIC_STIR) on page 127:
- 0: Disable
- 1: Enable.

Bit 0 NONBASETHRDENA
Configures how the processor enters Thread mode.
- 0: Processor can enter Thread mode only when no exception is active.
- 1: Processor can enter Thread mode from any level under the control of an EXC_RETURN value, see Exception return on page 40.
**System handler priority register 1 (SCB_SHPR1)**

Bits 31:24 **PRI_11[7:0]**: Priority of system handler 11, SVCall

Bits 23:0 Reserved, must be kept cleared
System handler priority register 3 (SCB_SHPR3)

Address: 0xE000 ED20
Reset value: 0x0000 0000
Required privilege: Privileged

The SHCSR enables the system handlers, and indicates:
- The pending status of the bus fault, memory management fault, and SVC exceptions
- The active status of the system handlers.

If you disable a system handler and the corresponding fault occurs, the processor treats the fault as a hard fault.

You can write to this register to change the pending or active status of system exceptions. An OS kernel can write to the active bits to perform a context switch that changes the current exception type.

- Software that changes the value of an active bit in this register without correct adjustment to the stacked content can cause the processor to generate a fault exception. Ensure software that writes to this register retains and subsequently restores the current active status.
- After you have enabled the system handlers, if you have to change the value of a bit in this register you must use a read-modify-write procedure to ensure that you change only the required bit.

| Bits 31:24 PRI_15[7:0]: Priority of system handler 15, SysTick exception |
|-----------------------------|-----------------------------|
| Bits 23:16 PRI_14[7:0]: Priority of system handler 14, PendSV |
| Bits 15:0 Reserved, must be kept cleared |

4.4.8 System handler control and state register (SCB_SHCSR)

Address offset: 0x24
Reset value: 0x0000 0000
Required privilege: Privileged

The SHCSR enables the system handlers, and indicates:
- The pending status of the bus fault, memory management fault, and SVC exceptions
- The active status of the system handlers.

If you disable a system handler and the corresponding fault occurs, the processor treats the fault as a hard fault.

You can write to this register to change the pending or active status of system exceptions. An OS kernel can write to the active bits to perform a context switch that changes the current exception type.

- Software that changes the value of an active bit in this register without correct adjustment to the stacked content can cause the processor to generate a fault exception. Ensure software that writes to this register retains and subsequently restores the current active status.
- After you have enabled the system handlers, if you have to change the value of a bit in this register you must use a read-modify-write procedure to ensure that you change only the required bit.
Bits 31:19 Reserved, must be kept cleared

- **Bit 18** **USGFAULTENA**: Usage fault enable bit, set to 1 to enable\(^1\)
- **Bit 17** **BUSFAULTENA**: Bus fault enable bit, set to 1 to enable\(^1\)
- **Bit 16** **MEMFAULTENA**: Memory management fault enable bit, set to 1 to enable\(^1\)
- **Bit 15** **SVCALLPENDED**: SVC call pending bit, reads as 1 if exception is pending\(^2\)
- **Bit 14** **BUSFAULTPENDED**: Bus fault exception pending bit, reads as 1 if exception is pending\(^2\)
- **Bit 13** **MEMFAULTPENDED**: Memory management fault exception pending bit, reads as 1 if exception is pending\(^2\)
- **Bit 12** **USGFAULTPENDED**: Usage fault exception pending bit, reads as 1 if exception is pending\(^2\)
- **Bit 11** **SYSTICKACT**: SysTick exception active bit, reads as 1 if exception is active\(^3\)
- **Bit 10** **PENDSVACT**: PendSV exception active bit, reads as 1 if exception is active
- **Bit 9** Reserved, must be kept cleared
- **Bit 8** **MONITORACT**: Debug monitor active bit, reads as 1 if Debug monitor is active
- **Bit 7** **SVCALLACT**: SVC call active bit, reads as 1 if SVC call is active

Bits 6:4 Reserved, must be kept cleared

- **Bit 3** **USGFAULTACT**: Usage fault exception active bit, reads as 1 if exception is active
- **Bit 2** Reserved, must be kept cleared
- **Bit 1** **BUSFAULTACT**: Bus fault exception active bit, reads as 1 if exception is active
- **Bit 0** **MEMFAULTACT**: Memory management fault exception active bit, reads as 1 if exception is active

1. Enable bits, set to 1 to enable the exception, or set to 0 to disable the exception.
2. Pending bits, read as 1 if the exception is pending, or as 0 if it is not pending. You can write to these bits to change the pending status of the exceptions.
3. Active bits, read as 1 if the exception is active, or as 0 if it is not active. You can write to these bits to change the active status of the exceptions, but see the Caution in this section.
4.4.9 Configurable fault status register (SCB_CFSR)

Address offset: 0x28
Reset value: 0x0000 0000
Required privilege: Privileged

The CFSR is byte accessible. You can access the CFSR or its subregisters as follows:
- Access the complete CFSR with a word access to 0xE000ED28
- Access the MMFSR with a byte access to 0xE000ED28
- Access the MMFSR and BFSR with a halfword access to 0xE000ED28
- Access the BFSR with a byte access to 0xE000ED29
- Access the UFSR with a halfword access to 0xE000ED2A.

The CFSR indicates the cause of a memory management fault, bus fault, or usage fault.

Figure 20. CFSR subregisters

Reserved

- Bit 25 DIVBYZERO: Divide by zero usage fault
- When the processor sets this bit to 1, the PC value stacked for the exception return points to the instruction that performed the divide by zero.
- Enable trapping of divide by zero by setting the DIV_0_TRP bit in the CCR to 1, see Configuration and control register (SCB_CCR) on page 136.
- 0: No divide by zero fault, or divide by zero trapping not enabled
- 1: The processor has executed an SDIV or UDIV instruction with a divisor of 0.

- Bit 24 UNALIGNED: Unaligned access usage fault:
- Enable trapping of unaligned accesses by setting the UNALIGN_TRP bit in the CCR to 1, see Configuration and control register (SCB_CCR) on page 136.
- Unaligned LDM, STM, LDRD, and STRD instructions always fault irrespective of the setting of UNALIGN_TRP.
- 0: No unaligned access fault, or unaligned access trapping not enabled
- 1: The processor has made an unaligned memory access.

Bits 31:26 Reserved, must be kept cleared

Bits 23:20 Reserved, must be kept cleared
Bit 19 **NOCP**: No coprocessor usage fault. The processor does not support coprocessor instructions:
- 0: No usage fault caused by attempting to access a coprocessor
- 1: the processor has attempted to access a coprocessor.

Bit 18 **INVPC**: Invalid PC load usage fault, caused by an invalid PC load by EXC_RETURN:
When this bit is set to 1, the PC value stacked for the exception return points to the instruction that tried to perform the illegal load of the PC.
- 0: No invalid PC load usage fault
- 1: The processor has attempted an illegal load of EXC_RETURN to the PC, as a result of an invalid context, or an invalid EXC_RETURN value.

Bit 17 **INVSTATE**: Invalid state usage fault:
When this bit is set to 1, the PC value stacked for the exception return points to the instruction that attempted the illegal use of the EPSR.
This bit is not set to 1 if an undefined instruction uses the EPSR.
- 0: No invalid state usage fault
- 1: The processor has attempted to execute an instruction that makes illegal use of the EPSR.

Bit 16 **UNDEFINSTR**: Undefined instruction usage fault:
When this bit is set to 1, the PC value stacked for the exception return points to the undefined instruction.
An undefined instruction is an instruction that the processor cannot decode.
- 0: No undefined instruction usage fault
- 1: The processor has attempted to execute an undefined instruction.

Bit 15 **BFARVALID**: Bus Fault Address Register (BFAR) valid flag:
The processor sets this bit to 1 after a bus fault where the address is known. Other faults can set this bit to 0, such as a memory management fault occurring later.
If a bus fault occurs and is escalated to a hard fault because of priority, the hard fault handler must set this bit to 0. This prevents problems if returning to a stacked active bus fault handler whose BFAR value has been overwritten.
- 0: Value in BFAR is not a valid fault address
- 1: BFAR holds a valid fault address.

Bits 14:13 Reserved, must be kept cleared

Bit 12 **STKERR**: Bus fault on stacking for exception entry
When the processor sets this bit to 1, the SP is still adjusted but the values in the context area on the stack might be incorrect. The processor does not write a fault address to the BFAR.
- 0: No stacking fault
- 1: Stacking for an exception entry has caused one or more bus faults.

Bit 11 **UNSTKERR**: Bus fault on unstacking for a return from exception
This fault is chained to the handler. This means that when the processor sets this bit to 1, the original return stack is still present. The processor does not adjust the SP from the failing return, does not performed a new save, and does not write a fault address to the BFAR.
- 0: No unstacking fault
- 1: Unstack for an exception return has caused one or more bus faults.
Bit 10 IMPRECISERR: Imprecise data bus error
When the processor sets this bit to 1, it does not write a fault address to the BFAR.
This is an asynchronous fault. Therefore, if it is detected when the priority of the current
process is higher than the bus fault priority, the bus fault becomes pending and becomes
active only when the processor returns from all higher priority processes. If a precise fault
occurs before the processor enters the handler for the imprecise bus fault, the handler detects
both IMPRECISERR set to 1 and one of the precise fault status bits set to 1.
0: No imprecise data bus error
1: A data bus error has occurred, but the return address in the stack frame is not related to
the instruction that caused the error.

Bit 9 PRECISERR: Precise data bus error
When the processor sets this bit is 1, it writes the faulting address to the BFAR.
0: No precise data bus error
1: A data bus error has occurred, and the PC value stacked for the exception return points to
the instruction that caused the fault.

Bit 8 IBUSERR: Instruction bus error
The processor detects the instruction bus error on prefetching an instruction, but it sets the
IBUSERR flag to 1 only if it attempts to issue the faulting instruction.
When the processor sets this bit is 1, it does not write a fault address to the BFAR.
0: No instruction bus error
1: Instruction bus error.

Bit 7 MMARVALID: Memory Management Fault Address Register (MMAR) valid flag
If a memory management fault occurs and is escalated to a hard fault because of priority, the
hard fault handler must set this bit to 0. This prevents problems on return to a stacked active
memory management fault handler whose MMAR value has been overwritten.
0: Value in MMAR is not a valid fault address
1: MMAR holds a valid fault address.

Bits 6:5 Reserved, must be kept cleared

Bit 4 MSTKERR: Memory manager fault on stacking for exception entry
When this bit is 1, the SP is still adjusted but the values in the context area on the stack might
be incorrect. The processor has not written a fault address to the MMAR.
0: No stacking fault
1: Stacking for an exception entry has caused one or more access violations.

Bit 3 MUNSTKERR: Memory manager fault on unstacking for a return from exception
This fault is chained to the handler. This means that when this bit is 1, the original return stack
is still present. The processor has not adjusted the SP from the failing return, and has not
performed a new save. The processor has not written a fault address to the MMAR.
0: No unstacking fault
1: Unstack for an exception return has caused one or more access violations.
### 4.4.10 Hard fault status register (SCB_HFSR)

Address offset: 0x2C

Reset value: 0x0000 0000

Required privilege: Privileged

The HFSR gives information about events that activate the hard fault handler.

This register is read, write to clear. This means that bits in the register read normally, but writing 1 to any bit clears that bit to 0.

<table>
<thead>
<tr>
<th>Bit 31</th>
<th>DEBUG_VT: Reserved for Debug use. When writing to the register you must write 0 to this bit, otherwise behavior is unpredictable.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bit 30</td>
<td>FORCED: Forced hard fault Indicates a forced hard fault, generated by escalation of a fault with configurable priority that cannot be handled, either because of priority or because it is disabled. When this bit is set to 1, the hard fault handler must read the other fault status registers to find the cause of the fault. 0: No forced hard fault 1: Forced hard fault.</td>
</tr>
</tbody>
</table>
Bits 29:2  Reserved, must be kept cleared

Bit 1  **VECTBL**: Vector table hard fault
Indicates a bus fault on a vector table read during exception processing:
This error is always handled by the hard fault handler.
When this bit is set to 1, the PC value stacked for the exception return points to the instruction
that was preempted by the exception.
0: No bus fault on vector table read
1: Bus fault on vector table read.

Bit 0  Reserved, must be kept cleared
4.4.11 Memory management fault address register (SCB_MMFAR)

Address offset: 0x34
Reset value: undefined
Required privilege: Privileged

MMFAR[15:0]

Bits 31:0 **MMFAR[31:0]:** Memory management fault address

When the MMARVALID bit of the MMFSR is set to 1, this field holds the address of the location that generated the memory management fault.

When an unaligned access faults, the address is the actual address that faulted. Because a single read or write instruction can be split into multiple aligned accesses, the fault address can be any address in the range of the requested access size.

Flags in the MMFSR register indicate the cause of the fault, and whether the value in the MMFAR is valid. See *Configurable fault status register (SCB_CFSR)* on page 141.

<th>1</th>
<th>0</th>
</tr>
</thead>
</table>

BFAR[15:0]

Bits 31:0 **BFAR[31:0]:** Bus fault address

When the BFARVALID bit of the BFSR is set to 1, this field holds the address of the location that generated the bus fault.

When an unaligned access faults the address in the BFAR is the one requested by the instruction, even if it is not the address of the fault.

Flags in the BFSR register indicate the cause of the fault, and whether the value in the BFAR is valid. See *Configurable fault status register (SCB_CFSR)* on page 141.
4.4.13 System control block design hints and tips

Ensure software uses aligned accesses of the correct size to access the system control block registers:

- except for the CFSR and SHPR1-SHPR3, it must use aligned word accesses
- for the CFSR and SHPR1-SHPR3 it can use byte or aligned halfword or word accesses.

The processor does not support unaligned accesses to system control block registers.

In a fault handler, to determine the true faulting address:
1. Read and save the MMFAR or BFAR value.
2. Read the MMARVALID bit in the MMFSR, or the BFARVALID bit in the BFSR. The MMFAR or BFAR address is valid only if this bit is 1.

Software must follow this sequence because another higher priority exception might change the MMFAR or BFAR value. For example, if a higher priority handler preempts the current fault handler, the other fault might change the MMFAR or BFAR value.

4.4.14 SCB register map

The table provides shows the System control block register map and reset values. The base address of the SCB register block is 0xE000 ED00.

<table>
<thead>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
4.5 SysTick timer (STK)

The processor has a 24-bit system timer, SysTick, that counts down from the reload value to zero, reloads (wraps to) the value in the LOAD register on the next clock edge, then counts down on subsequent clocks.

When the processor is halted for debugging the counter does not decrement.

4.5.1 SysTick control and status register (STK_CTRL)

Address offset: 0x00
Reset value: 0x0000 0004
Required privilege: Privileged

The SysTick CTRL register enables the SysTick features.
Bits 31:17 Reserved, must be kept cleared.

Bit 16 **COUNTFLAG:**
Returns 1 if timer counted to 0 since last time this was read.

Bits 15:3 Reserved, must be kept cleared.

Bit 2 **CLKSOURCE:** Clock source selection
Selects the clock source.
0: AHB/8
1: Processor clock (AHB)

Bit 1 **TICKINT:** SysTick exception request enable
0: Counting down to zero does not assert the SysTick exception request
1: Counting down to zero to asserts the SysTick exception request.

*Note: Software can use COUNTFLAG to determine if SysTick has ever counted to zero.*

Bit 0 **ENABLE:** Counter enable
Enables the counter. When ENABLE is set to 1, the counter loads the RELOAD value from the LOAD register and then counts down. On reaching 0, it sets the COUNTFLAG to 1 and optionally asserts the SysTick depending on the value of TICKINT. It then loads the RELOAD value again, and begins counting.

0: Counter disabled
1: Counter enabled

### 4.5.2 SysTick reload value register (STK_LOAD)

</tr>
</tbody>
</table>
Bits 31:24  Reserved, must be kept cleared.

Bits 23:0  **RELOAD[23:0]: RELOAD value**

The LOAD register specifies the start value to load into the VAL register when the counter is enabled and when it reaches 0.

**Calculating the RELOAD value**

The RELOAD value can be any value in the range 0x00000001-0x00FFFFFF. A start value of 0 is possible, but has no effect because the SysTick exception request and COUNTFLAG are activated when counting from 1 to 0.

The RELOAD value is calculated according to its use:

- To generate a multi-shot timer with a period of \( N \) processor clock cycles, use a RELOAD value of \( N-1 \). For example, if the SysTick interrupt is required every 100 clock pulses, set RELOAD to 99.

- To deliver a single SysTick interrupt after a delay of \( N \) processor clock cycles, use a RELOAD of value \( N \). For example, if a SysTick interrupt is required after 400 clock pulses, set RELOAD to 400.
4.5.3 SysTick current value register (STK_VAL)

Address offset: 0x08
Reset value: 0x0000 0000
Required privilege: Privileged

Bits 31:24 Reserved, must be kept cleared.
Bits 23:0 CURRENT[23:0]: Current counter value
The VAL register contains the current value of the SysTick counter.
Reads return the current value of the SysTick counter.
A write of any value clears the field to 0, and also clears the COUNTFLAG bit in the STK_CTRL register to 0.

4.5.4 SysTick calibration value register (STK_CALIB)

Address offset: 0x0C
Reset value: 0x0002328
Required privilege: Privileged
The CALIB register indicates the SysTick calibration properties.

Bit 31 NOREF: NOREF flag
Reads as zero. Indicates that a separate reference clock is provided. The frequency of this clock is HCLK/8.
Bit 30 **SKEW**: SKEW flag
Reads as one. Calibration value for the 1 ms inexact timing is not known because TENMS is not known. This can affect the suitability of SysTick as a software real time clock.

Bits 29:24 Reserved, must be kept cleared.

Bits 23:0 **TENMS[23:0]**: Calibration value
Indicates the calibration value when the SysTick counter runs on HCLK max/8 as external clock. The value is product dependent, please refer to the Product Reference Manual, SysTick Calibration Value section. When HCLK is programmed at the maximum frequency, the SysTick period is 1ms.
If calibration information is not known, calculate the calibration value required from the frequency of the processor clock or external clock.

### 4.5.5 SysTick design hints and tips
The SysTick counter runs on the processor clock. If this clock signal is stopped for low power mode, the SysTick counter stops.
Ensure software uses aligned word accesses to access the SysTick registers.

### 4.5.6 SysTick register map
The table provides shows the SysTick register map and reset values. The base address of the SysTick register block is 0xE000 E010.
